Type Package

Title Periodically Correlated and Periodically Integrated Time Series

Description Classes and methods for modelling and simulation of periodically correlated (PC) and periodically integrated time series. Compute theoretical periodic autocovariances and related properties of PC autoregressive moving average models. Some original methods including Boshnakov & Iqelan (2009) <[doi:10.1111/j.1467-9892.2009.00617.x](https://doi.org/10.1111/j.1467-9892.2009.00617.x)>, Boshnakov (1996) <[doi:10.1111/j.1467-9892.1996.tb00281.x](https://doi.org/10.1111/j.1467-9892.1996.tb00281.x)>.

*Periodically Correlated and Periodically Integrated Time Series***Description**

Classes and methods for modelling and simulation of periodically correlated (PC) and periodically integrated time series. Compute theoretical periodic autocovariances and related properties of PC autoregressive moving average models. Some original methods including Boshnakov & Iqelan (2009) <doi:10.1111/j.1467-9892.2009.00617.x>, Boshnakov (1996) <doi:10.1111/j.1467-9892.1996.tb00281.x>.

Details

The underlying assumption is that the observations are made at regular intervals, such as quarter, month, week, day — or represent data for such intervals — and these intervals are nested into larger periods. In `pcts` we call the larger period a cycle and its parts seasons. Typical examples of season-cycle timing are months in a year, quarters in a year, days in a week (or business week). The number of seasons in a cycle is called frequency in class "ts" in base R.

Cycles in `pcts` keep not only the number of seasons (frequency) but other information, such as the names of the seasons and units of seasons. In `pcts` there are a number of builtin cycle classes for typical cases, as well as provision for creation of custom cycles on the fly. See `pcCycle` and `BuiltinCycle` for ways to create cycle objects, and `allSeasons` for further examples.

Periodic time series can be created with `pcts`, which accepts as input vectors, matrices and time series objects from base R and some other packages, including `zoo` and `xts`. When importing data, the time information is taken from the data and an attempt is made to guess the periodicity from the frequency (for time series objects that have it set) and an analysis of the datetime stamps, if present. `pcts` also has arguments for specifying the number of seasons or the cycle, as well as the start datetime.

The main periodic time series classes in `pcts` are `PeriodicTS` and `PeriodicMTS`, for univariate and multivariate time series, respectively. Standard base-R time series functions can be used with them directly, see for example `window`, `frequency`, `cycle`, `time`, `deltat`, `start`, `end`, `boxplot`, `monthplot`, `na.trim` (`na.trim` is from package `zoo`).

Methods for `plot`, `summary`, `print`, `show`, `head`, `tail`, and other base-R functions are defined where suitable. Examples can be found in section Examples and in help pages for the corresponding functions, classes and methods.

The naming conventions are as follows. Names of classes generally consists of one or more words. The first letter of each word, is capitalised. Only the first letter of abbreviations for models, such as ARMA, is capitalised. Similarly for generic functions but for them the first word is not capitalised. In a few names PM stands for 'periodic model' and TS for 'time series'.

Significant portion of the code was written in 2005–2007. Many of the functions and classes have been renamed under the above conventions and most of those that are not are not exported but a few still are and they should be considered subject to change.

`autocovariances`, `autocorrelations`, `partialAutocorrelations` and others are one-stop generic functions for computation of properties of time series and models. What to compute is deduced from the type of the object. For models they compute theoretical quantities — periodic or non-periodic, scalar or multivariate. For time series they compute the corresponding sample counterparts.

```

Description

Functions and methods to get names of seasons and related quantities for objects from the cycle, periodic time series classes and other objects for which the concepts are defined.

Usage

```
unitSeason(x)
unitCycle(x)
seqSeasons(x)
allSeasons(x, abb = FALSE, prefix = "S", ...)

unitSeason ( x, ... ) <- value
unitCycle ( x, ... ) <- value
allSeasons ( x, abb, ... ) <- value

## S4 replacement method for signature 'SimpleCycle'
allSeasons(x, abb, prefix, ...) <- value

## S4 replacement method for signature 'Cyclic'
allSeasons(x, abb = FALSE, ...) <- value
```

Arguments

x	a cycle, time series or other object for which the concept of seasons is defined.
abb	if TRUE give the abbreviated names of the seasons.
prefix	use this prefix for automatically generated names of seasons.
...	further arguments for methods.
value	a character string

Details

The cycle classes, i.e. classes inheriting from class `BasicCycle`, provide common functionality. In particular, they guarantee that the functions described in this topic are available. These functions work also for the periodic time series classes and may be defined for other classes where they make sense.

Methods

Methods for `allSeasons()`:

```
signature(x = "BasicCycle", abb = "ANY")
signature(x = "DayWeekCycle", abb = "logical")
signature(x = "DayWeekCycle", abb = "missing")
signature(x = "MonthYearCycle", abb = "logical")
signature(x = "MonthYearCycle", abb = "missing")
signature(x = "OpenCloseCycle", abb = "logical")
```

```
signature(x = "OpenCloseCycle", abb = "missing")
signature(x = "QuarterYearCycle", abb = "logical")
signature(x = "QuarterYearCycle", abb = "missing")
signature(x = "SimpleCycle", abb = "ANY")
signature(x = "Cyclic", abb = "ANY")
signature(x = "Every30MinutesCycle", abb = "logical")
signature(x = "Every30MinutesCycle", abb = "missing")
signature(x = "VirtualPeriodicModel", abb = "ANY")
```

Author(s)

Georgi N. Boshnakov

Examples

```
opcycle <- new("OpenCloseCycle")
## convert to SimpleCycle to change some names
siopcycle <- as(opcycle, "SimpleCycle")
## siopcycle inherits names from opcycle
unitSeason(siopcycle)      # "Season"
unitCycle(siopcycle)      # "Cycle"
allSeasons(siopcycle)     # "Open" "Close"
allSeasons(siopcycle, abb = TRUE) # "O" "C"

allSeasons(siopcycle) <- c("Day", "Night")
allSeasons(siopcycle) # now: "Day" "Night"
## change also abbreviations
allSeasons(siopcycle, abb = TRUE) <- c("D", "N")
allSeasons(siopcycle, abb = TRUE) # now: "D" "N"

seasons <- new("SimpleCycle", 4)
unitSeason(seasons)      # "Season"
unitCycle(seasons)      # "Cycle"
allSeasons(seasons)
allSeasons(seasons, abb = TRUE)

unitCycle(seasons) <- "Year"
unitCycle(seasons)
allSeasons(seasons) <- c("Winter", "Spring", "Summer", "Autumn")
allSeasons(seasons)
allSeasons(seasons, abb = TRUE) <- c("Win", "Spr", "Sum", "Aut")
allSeasons(seasons, abb = TRUE)

## change autumn to Fall
allSeasons(seasons)[4] <- "Fall"
allSeasons(seasons, abb = TRUE)[4] <- "Fal"
allSeasons(seasons)
allSeasons(seasons, abb = TRUE)

## indexing of cycle objects is equivalent to allSeasons.
```

```
seasons[]
seasons[ , abb = TRUE]

seasons[4] <- "Herbst"
seasons

unitCycle(seasons) <- "Jahre"
unitCycle(seasons)
unitSeason(seasons) <- "Jahreszeit"
seasons[] <- c("Winter", "Fruehling", "Sommer", "Herbst")
seasons[ , abb = TRUE] <- c("W", "F", "S", "H")
seasons[]
seasons
```

as_date-methods *Replace methods for as_date in package pcts*

Description

Replace methods for as_date in package pcts.

Methods

```
signature(x = "PeriodicTimeSeries")
signature(x = "ANY")
signature(x = "character")
signature(x = "Cyclic")
signature(x = "numeric")
signature(x = "POSIXt")
```

as_datetime-methods *Methods for as_datetime in package pcts*

Description

Methods for as_datetime in package pcts.

Methods

```
signature(x = "PeriodicTimeSeries")
```

autocorrelations-methods

Compute autocorrelations and periodic autocorrelations

Description

Methods for computation of autocorrelations and periodic autocorrelations.

Methods

```
signature(x = "numeric", maxlag = "ANY", lag_0 = "missing")
signature(x = "PeriodicTimeSeries", maxlag = "ANY", lag_0 = "missing")
signature(x = "PeriodicAutocovariances", maxlag = "ANY", lag_0 = "missing")
signature(x = "SamplePeriodicAutocovariances", maxlag = "ANY", lag_0 = "missing")
signature(x = "VirtualPeriodicAutocovariances", maxlag = "ANY", lag_0 = "missing")
signature(x = "VirtualPeriodicAutocovarianceModel", maxlag = "ANY", lag_0 = "missing")
```

See Also

[autocorrelations](#) in package **sarima** for further details.

[autocovariances](#) for autocovariances;

Examples

```
## periodic ts object => peridic acf
autocorrelations(pcts(AirPassengers), maxlag = 10)

## for "ts" or "numeric" objects the default is non-periodic acf
autocorrelations(AirPassengers, maxlag = 10)
autocorrelations(as.numeric(AirPassengers))
## argument 'nseasons' forces periodic acf
autocorrelations(AirPassengers, maxlag = 10, nseasons = 12)
autocorrelations(as.numeric(AirPassengers), maxlag = 10, nseasons = 12)
```

autocovariances-methods

Compute autocovariances and periodic autocovariances

Description

Methods for the generic function `autocovariances()`, which computes autocovariances meaningful for the first argument. For objects representing time series, it computes sample autocovariances (univariate, multivariate, periodic, as appropriate). For objects representing models, it computes the relevant theoretical autocovariances.

Methods

```
signature(x = "matrix", maxlag = "ANY")
signature(x = "numeric", maxlag = "ANY")
signature(x = "PeriodicArmaModel", maxlag = "ANY")
signature(x = "PeriodicArModel", maxlag = "ANY")
signature(x = "PeriodicAutocovarianceModel", maxlag = "ANY")
signature(x = "PeriodicTS", maxlag = "ANY")
signature(x = "VirtualPeriodicAutocovariances", maxlag = "ANY")
```

If `maxlag` is missing or equal to `maxLag(x)`, `x` is returned unchanged. Otherwise the number of available lags is adjusted to `maxlag`.

See Also

[autocovariances](#) in package **sarima** for further details.
[autocorrelations](#) for autocorrelations;

Examples

```
## periodic ts object => peridic acvf
autocovariances(pcts(AirPassengers), maxlag = 10)

## for "ts" or "numeric" objects the default is non-periodic acvf
autocovariances(AirPassengers, maxlag = 10)
autocovariances(as.numeric(AirPassengers))
## argument 'nseasons' forces periodic acvf
autocovariances(AirPassengers, maxlag = 10, nseasons = 12)
autocovariances(as.numeric(AirPassengers), maxlag = 10, nseasons = 12)
```

availStart	<i>Time of first or last non-NA value</i>
------------	---

Description

Time of first or last non-NA value.

Usage

```
availStart(x, any = TRUE)

availEnd(x, any = TRUE)
```

Arguments

<code>x</code>	a time series or similar object
<code>any</code>	logical flag for multivariate objects. The default TRUE requests the first/last index containing any non-NA value. FALSE requires that all values at the first/last index must be non-NA.

Details

The time is given as a cycle-season pair.

Argument `any` is meaningful only for multivariate objects. Its name is short for "the first/last index for which any of the values (ie at least one) is non-NA". `any = FALSE` is taken to mean that the index is the first/last for which all values are non-NA.

The functions can be used together with windows to trim NA's from the beginning and/or end of the data. As an alternative we provide also methods for periodic time series methods for `zoo::na.trim`, see the examples below.

Value

numeric, length 2

BareCycle-class

Class BareCycle

Description

Class BareCycle.

Objects from the Class

Objects can be created by calls of the form `pcCycle(nseasons)` or `new("BareCycle", nseasons)`.

Class "BareCycle" represents the number of seasons and is sufficient for many computations.

Slots

nseasons: Object of class "integer", the number of seasons.

Extends

Class "[BasicCycle](#)", directly.

Methods

initialize signature(.Object = "BareCycle"): ...

coerce signature(from = "BareCycle", to = "SimpleCycle"): ...

coerce signature(from = "BuiltinCycle", to = "BareCycle"): ...

nSeasons signature(object = "BareCycle"): ...

show signature(object = "BareCycle"): ...

Author(s)

Georgi N. Boshnakov

[DayWeekCycle-class](#), [MonthYearCycle-class](#), [OpenCloseCycle-class](#), [QuarterYearCycle-class](#)
[PartialCycle-class](#),
[BasicCycle-class](#) (virtual, for use in signatures)

Examples

```
pcCycle(5)
cycle <- new("BareCycle", 5)
identical(new("BareCycle", 5), pcCycle(5)) # TRUE

unitSeason(cycle)
unitCycle(cycle)
allSeasons(cycle)
seqSeasons(cycle)

cycle[]
cycle[3]

## if cycle represents 5-days week one may prefer:
BuiltinCycle(5)
```

BasicCycle-class	<i>Class BasicCycle</i>
------------------	-------------------------

Description

Virtual class "BasicCycle" is a class union that can be used in signatures of methods and classes when any of the cycle classes is admissible as argument or slot.

Objects from the Class

A virtual Class: No objects may be created from it.

Methods

```
[ signature(x = "BasicCycle", i = "ANY", j = "missing", drop = "ANY")
[ signature(x = "BasicCycle", i = "missing", j = "missing", drop = "ANY")
[<- signature(x = "BasicCycle", i = "ANY", j = "missing", value = "ANY")
[<- signature(x = "BasicCycle", i = "missing", j = "missing", value = "ANY")
```

```

date<- signature(x = "BasicCycle"): ...
allSeasons signature(x = "BasicCycle", abb = "ANY")
seqSeasons signature(x = "BasicCycle")
pcCycle signature(x = "BasicCycle", type = "character"): ...
pcCycle signature(x = "BasicCycle", type = "missing"): ...
pcts signature(x = "matrix", nseasons = "BasicCycle"): ...
pcts signature(x = "numeric", nseasons = "BasicCycle"): ...

```

```
showClass("BasicCycle")
```

BuiltinCycle-class *Class "BuiltinCycle" and its subclasses in package 'pcts'*

Description

Class "BuiltinCycle" and its subclasses in package 'pcts'.

Objects from the Class

Class "BuiltinCycle" is a virtual Class: no objects may be created from it. Class "BuiltinCycle" has several built-in cycle subclasses. Objects from the subclasses can be created by calls of the form `new("className", first, ...)`, where "className" is the name of the subclass. The optional argument `first` can be used to designate a season to be considered first in the cycle, by default the first.

The function `BuiltinCycle` provides a more convenient way to generate objects from subclasses of class "BuiltinCycle". Its argument is the number of seasons.

These classes are effectively unmodifiable, but the user can convert them to other cycle classes, e.g. class "SimpleCycle", and adapt as needed.

The subclasses of "BuiltinCycle" have definitions for all methods promised by its superclass "BasicCycle".

Currently, the following builtin classes are defined:

Name	Description	nSeasons
"DayWeekCycle"	weekdays	7
"QuarterYearCycle"	quarters in a year	4
"MonthYearCycle"	months in a year	12
"Every30MinutesCycle"	half-hour intervals in a day	48
"OpenCloseCycle"	start/end of a working day	2

There is also a class "FiveDayWeekCycle" but it is deprecated and will be removed in the near future. Use `BuiltinCycle(5)` to create objects with equivalent functionality.

Slots

The class "BuiltinCycle" and its subclasses have a single common slot:

first: Object of class "integer", the index of the season to be treated as the first in a cycle.

Extends

Class "BuiltinCycle" extends class "BasicCycle", directly.

Classes "DayWeekCycle", "Every30MinutesCycle", "FiveDayWeekCycle", "OpenCloseCycle" and "QuarterYearCycle" extend:

Class "BuiltinCycle", directly. Class "BasicCycle", by class "BuiltinCycle", distance 2.

Methods

Functions with methods for this class:

coerce signature(from = "BuiltinCycle", to = "BareCycle"): ...

coerce signature(from = "BuiltinCycle", to = "SimpleCycle"): ...

initialize signature(.Object = "BuiltinCycle"): ...

show signature(object = "BuiltinCycle"): ...

The functions to extract properties from objects from the builtin cycle classes have identical signatures (except for the name of the class). For example, for "QuarterYearCycle" the methods are as follows:

allSeasons signature(x = "QuarterYearCycle", abb = "logical"): ...

allSeasons signature(x = "QuarterYearCycle", abb = "missing"): ...

nSeasons signature(object = "QuarterYearCycle"): ...

unitCycle signature(x = "QuarterYearCycle"): ...

unitSeason signature(x = "QuarterYearCycle"): ...

The methods for the remaining builtin classes are the same with "QuarterYearCycle" replaced suitably.

```

Cyclic *Create objects from class Cyclic*

Description

Create objects from class Cyclic.

Usage

```
Cyclic(cycle, start = NULL, ...)

## S3 method for class 'Cyclic'
as.Date(x, ...)

## S3 method for class 'Cyclic'
date(x)

## S3 method for class 'PeriodicTimeSeries'
as.Date(x, ...)
```

Arguments

cycle	a cycle object, a positive integer giving the number of seasons, or any other object that can be used to create a cycle with <code>pcCycle(x, ...)</code> .
start	a cycle-season pair, a datetime object, a Date object or any object that can be converted to datetime with <code>as_datetime(start)</code> .
...	for Cyclic, arguments passed to <code>pcCycle</code> , used only if cycle is not from a cycle class.
x	a Cyclic object

Value

for Cyclic, an object from class "Cyclic"

See Also

dataFranses1996	<i>Example data from Franses (1996)</i>
-----------------	---

Description

A multivariate time series containing the data used in examples by Franses (1996).

Usage

```
data("dataFranses1996")
```

Format

A multivariate quarterly time series.

Details

Each column is a quarterly time series. The time series start and end at different times, so NA's are used to align them in a single multivariate time series. Detailed account of the sources of the data is given by @FransesB1; Data Appendix), p. 214.

year (column 1)

The time formatted as yyyy.Q, where yyyy is the year and Q is the quarter (one of 1, 2, 3 or 4.). This column was part of the original data but is not really needed here since the time series object contains the time information.

USTotalIPI (column 2)

Total Industrial Production Index for the United States (1985 = 100), 1960.1–1991.4.

CanadaUnemployment (column 3)

Unemployment in Canada, measured in 1000 persons, 1960.1 - 1987.4.

- GermanyGNP (column 4)
Real GNP in Germany, 1960.1 - 1990.4 .
- UKTotalInvestment (column 5)
Real Total Investment in the United Kindom, 1955.1 - 1988.4.
- SA_USTotalIPI (column 6) Seasonally adjusted USTotalIPI.
- SA_CanadaUnemployment (column 7)
Seasonally adjusted CanadaUnemployment.
- SA_GermanyGNP (column 8)
Seasonally adjusted GermanyGNP.
- UKGDP (column 9)
United Kingdom gross domestic product (at 1985 prices), 1955.1–1988.4.
- UKTotalConsumption (column 10)
United Kingdom total consumption (at 1985 prices), 1955.1–1988.4.
- UKNondurablesConsumption (column 11)
United Kindom nondurables consumption (at 1985 prices), 1955.1–1988.4.
- UKExport (column 12)
United Kindom exports of goods and services (at 1985 prices), 1955.1–1988.4.
- UKImport (column 13)
United Kindom imports of goods and services (at 1985 prices), 1955.1–1988.4.
- UKPublicInvestment (column 14)
United Kindom public investment (at 1985 prices), 1962.1–1988.4.
- UKWorkforce (column 15)
United Kindom workforce (consisting of workforce in employment and unemployment), 1955.1–1988.4.
- SwedenNondurablesConsumption (column 16)
Real per capita non-durables consumption in Sweden (measured in logs), 1963.1–1988.1.
- SwedenDisposableIncome (column 17)
Real per capita disposable income in Sweden (measured in logs), 1963.1–1988.1.
- SA_SwedenNondurablesConsumption (column 18)
Seasonally adjusted SwedenNondurablesConsumption with Census X-11 method, 1964.1–1988.1. (Using the approximate linear Census X-11 filter given in Table 4.1, p. 52 in Franses (1996) and generating the forecasts and backcasts as described in Ooms (1994)).
- SA_SwedenDisposableIncome (column 19)
Seasonally adjusted SwedenDisposableIncome with Census X-11 method, 1964.1–1988.1. (Using the same method as above.)
- More details on the individual time series are given by Franses (1996).

Note

Most of the time series in dataFranses1996 are available as separate datasets in package ‘partsm’. The numbers should be the same but note that, at the time of writing this, not all datasets there carry complete time information.

Source

The data were downloaded from <http://people.few.eur.nl/franses/research/data/data1.txt>, but this link is now broken.

ex1f	<i>An example PAR autocorrelation function</i>
------	--

Description

ex1 is the autocorrelation function used in the reference as an example when the solution of the periodic Yule-Walker system gives an invalid PAR model. This can happen only if Lambert-Lacroix's condition on the PAR order is not satisfied, see `pdSafeParOrder`.

Format

A function of two arguments

Source

See pp. 429–430 of the reference.

References

Lambert-Lacroix S (2005). “Extension of autocovariance coefficients sequence for periodically correlated processes.” *Journal of Time Series Analysis*, **26**(6), pp. 423-435.

See Also

[pdSafeParOrder](#)

Examples

```

data(ex1f)
## compute the first few autocorrelations
pc3 <- slMatrix(period = 2, maxlag = 5, f = ex1f, type = "tt")
## Fir a PAR(0,2) model
res0p2 <- alg1(pc3[,c(0,2)])
## model is invalid since a partial autocorrelation is larger than one:
res0p2$be
## Find a modified order:
pdSafeParOrder(c(0,2)) # PAR(1,2)
## now the parcor's are fine:
res1p2 <- alg1(pc3[,c(1,2)])
res1p2$be

```

filterCoef-methods *Get the coefficients of a periodic filter*

Description

Get the coefficients of a periodic filter.

Details

filterCoef is a generic function to extract the coefficients of periodic filters. Argument convention can be used to force a particular convention for the signs. The description here is for the methods defined in this package.

If convention is missing, the coefficient matrix is returned as stored in the object. Otherwise, if convention is one of the strings "BJ", "--" or "-", the coefficients returned have the opposite sign of those in the auxilliary polynomial (Box-Jenkins' convention). If convention is one of "SP", "++" or "+", the coefficients are as in the auxilliary polynomial (convention used in signal processing).

Value

a matrix

Methods

```
signature(object = "PeriodicBJFilter", convention = "character")
```

```
signature(object = "PeriodicSPFilter", convention = "character")
```

See Also

[filterCoef](#) for further details;

fitPM

Fit periodic time series models

Description

Generic function with methods for fitting periodic time series models.

Usage

```
fitPM( model, x, ...)
```

Arguments

x	the time series.
model	a periodic model, see Details.
...	further arguments to be passed on to individual methods.

Details

This is a generic function.

model provides the specification of the model. In particular, the class of model determines what model is fitted. Specific values of the parameters are generally ignored by non-iterative methods but some methods can handle more detailed specifications, see the individual methods.

Value

the fitted model, typically an object of class `class(model)`

Methods

`signature(model = "ANY", x = "ANY")` This is the default method. It simply exits with an error message stating that `fitPM` does not have a method for the model specified by `model`.

`signature(model = "numeric", x = "ANY")` Fits a PAR model to `x`. `model` should be a vector of non-negative integers giving the PAR order. The length of this vector is taken to be the number of seasons.

This is a convenience method. It constructs a PAR model and calls the method for `model = "PeriodicArModel"`.

`signature(model = "PeriodicArModel", x = "ANY")` Fits a PAR model.

`signature(model = "mcSpec", x = "ANY")` Fits a periodic model according to the specification given by `model`.

Currently this method uses `mC.ss` to set up the optimisation environment and then calls one of the optimisation functions in that environment as specified by argument `optim.method`, see below.

Additional arguments may be specified to control the optimisation.

Argument `init` can be used to give initial values. It is passed on to `mC.ss` (and so has the format required by it).

`optim.method` is the name of an optimisation function in the environment returned by `mC.ss`. The default is `optim.method = "minim"`, which is based on the standard R function `optim`. Alternatives are `"minimBB"` or `"minimBBLU"`. All this needs to be documented but see `mC.ss` and `xx.ss` for details.

Further arguments are passed on to the optimisation method. A typical argument supported by most optimisation functions is `control`.

`signature(model = "PiPeriodicArModel", x = "ANY")` Fits a periodically integrated PAR model using the parameters of `model` as initial values. Calls `pclspiar` to do the actual work.

`signature(model = "SiPeriodicArModel", x = "ANY")` Fits a seasonally integrated PAR model.

`signature(model = "PeriodicArModel", x = "PeriodicMTS")`

`signature(model = "PeriodicArModel", x = "PeriodicTS")`

fit_trigPAR_optim *Fit a subset trigonometric PAR model*

Description

Fit a subset PAR model with trigonometric parameterisation.

Usage

```
fit_trigPAR_optim(x, order, nseasons, seasonof1st = 1, maxiter = 200,
                 harmonics = NULL, sintercept = FALSE, tol = 1e-07,
                 type = c("vecbyrow", "bylag"), verbose = TRUE)
```

Arguments

x	time series.
order	order, an integer number.
nseasons	number of seasons, an integer number.
seasonof1st	season of the first observation.
maxiter	max number of iterations.
harmonics	the harmonics to include in the model, vector of non-negative integers.
sintercept	if TRUE include seasonal intercept.
tol	when to stop the iterations.
type	type of parameterisation, currently one of "vecbyrow" or "bylag".
verbose	if TRUE print more details during estimation.

Details

Fits a subset PAR model using trigonometric parameterisation, i.e. Fourier series for the periodic coefficients written in terms of sines and cosines.

If argument type is bylag, the parameters for each lag are parameterised independently from other lags. If sintercept is TRUE, it has its own trigonometric representation.

If argument type is vecbyrow ("Vec operation by row"), the PAR parameters are stacked in a vector with all parameters for the first season, followed by all parameters for the second, and so on. The trigonometric parameterisation for this vector is used. So the fundamental frequency is $1/(nseasons * order)$. If sintercept is TRUE when type = vecbyrow, then the intercept for each season is put before the PAR parameters and the fundamental frequency becomes $1/(nseasons * (order + 1))$. Putting together the intercepts and the PAR parameters may not be very useful for parsimonious trigonometric parameterisation, so to have a separate set of coefficients for the intercepts set attribute "merge" of sintercept to FALSE.

Value

an object from class [SubsetPM](#)

Note

This function may change.

Author(s)

Georgi N. Boshnakov

Examples

```
## see examples for class "SubsetPM"
```

```
four_stocks_since2016_01_01
```

Data for four stocks since 2016-01-01

Description

Data for four stocks since 2016-01-01.

Usage

```
data("four_stocks_since2016_01_01")
```

Format

A list with components "DELL", "MSFT", "INTC", "IBM". Each component is a time series from class "xts" "zoo".

Details

Stock market data for Dell, Microsoft, Intel and IBM, from 2016-01-01 to 2020-04-17. The Dell data start from 2016-08-17. All data were downloaded from Yahoo Finance on 2020-04-18.

Fraser2017

Fraser River at Hope, mean monthly flow

Description

Mean monthly flow (cms) of Fraser River From March 1912 to December 2017, recorded by Fraser River at Hope station.

Usage

```
data("Fraser2017")
```

Format

A time series (class "ts") with frequency 12, starting from January 1912 (the first two data values are NA) to December 2017.

Details

Dataset Fraser2017 is an extension of dataset "Fraser" in package "pear". The latter runs up to December 1990 (not the documented December 1991). At the time of writing this package "pear" is archived on CRAN, which is the main reason to include the dataset (with the added benefit of almost 30 years of additional data).

mC.ss

*Create environment for mc-fitting***Description**

Creates an environment for mc-fitting. These functions are transitory, hence the strange names.

Usage

```
mC.ss(spec, ...)
```

```
xx.ss(period, type.eigval, n.root, eigabs, eigsign, co_r, co_arg,
       init = NULL, len.block = NULL, mo.col, generators = NULL)
```

Arguments

spec	a model, an object of class mcSpec.
...	further arguments to be passed on to xx.ss.
period	the number of seasons.
type.eigval	types of the eigenvalues, a character vector with elements "r" or "cp", see Details.
n.root	number of roots. Currently the dimension of the matrix is set to this.
eigabs	The absolute values/moduli of the eigenvalues, numeric vector.
eigsign	The signs/moduli of the eigenvalues.
co_r	similar to eigabs but for the co parameters.
co_arg	similar to eigsign but for the co parameters.
init	initial values, see Details.
len.block	lengths of Jordan blocks.
mo.col	last non-zero column in the top of the matrix.
generators	~~ TODO: describe this argument. ~~

Details

mC.ss takes the specification of the model as an object of class mcSpec and calls xx.ss.

Basically, the value returned by these functions is an extended model specification together with an environment which can be used for fitting the model, exploring the results and trying various things. This may be used for getting better understanding of the model and the optimisation routines.

The result of both functions is a list, containing several functions and an environment. The environment (element env) is the most important element since it allows access to everything in the model environment. The function elements of the list are simply a convenience.

Several functions in env are available for fitting the model. Currently these are minim, minimBB and minimBBlu. The first argument of all these functions is a time series to which the model is

to be fitted. By default, a conditional likelihood is being optimised. To base the optimisation on conditional sum of squares, set argument `CONDLIK` to `FALSE`. The remaining arguments in a call to any of the above functions are passed on to the corresponding optimisation routine (whose help page should be consulted for details).

`minim` uses the core R function `optim`. `minimBB` and `minimBBlu` use `BBoptim` from package `BB`. They result is a list, as returned by the corresponding optimisation function with the optimal parameters in element `par`. The elements of this vector are named to help somewhat in its interpretation but complete information about the fitted model can be obtained from the environment.

Firstly, at the end of the optimisation, the optimal parameters and other information are stored in `env`. If the same call (maybe with modified instructions for the optimisation) is repeated, these parameters will be used as initial values for a new optimisation run. This may be useful, for example, if the previous run didn't converge.

Secondly, properties of the fitted model and more useful representations can be obtained using functions in the environment or the convenience functions in the list returned by `xx.ss`.

`optparam2mcp` converts a vector of parameters into the more familiar filter representation, where the *i*-th row contains the coefficients for the *i*-th season. This function takes one argument the vector of parameters, e.g. the one returned by the fitting functions. It updates a number of variables in `env`, computes the filter representation of the model and stores it in `wrkmodel`. It returns `NULL`. This function may be used for exploratory purposes or to set new values for the parameters, e.g. to be used as starting values for a new optimisation run.

`mcp2optparam` does the opposite. It converts the current model in `env` to a vector of parameter. This function does not have arguments.

`mclik` computes the value of the conditional likelihood for given parameters. Its first argument is a time series, the second is a vector of parameters and the third is a vector of innovations. Only the first argument is compulsory. If `param` is not supplied, the current parameters in `env` are used. Otherwise, they are updated with the new parameters and then used. The innovations default to the zero vector. `mcSS` is similar but computes the conditional sum of squares.

Argument `init` can be used to provide initial values. If it is missing or `NULL`, random initial values are generated for the free parameters. `init` may also be a numeric vector suitable for the call `optparam2mcp(init)`, see above. This vector would typically come from a previous optimisation run.

`init` may also be a list with elements `"eigabs"`, `"eigsign"`, `"co_r"`, `"co_abs"`. These components have the same meaning as the corresponding arguments of `xx.ss`.

TODO: more is needed here!

Value

A list with the following components:

<code>fmcss</code>	a function to compute the sum of squares for a model.
<code>fparamvec</code>	a function to convert mc-parameters to optimisation parameters.
<code>fmcp</code>	a function to convert optimisation parameters to mc-parameters.
<code>env</code>	an object of class environment

meanvarcheck

Asymptotic covariance matrix of periodic mean

Description

Asymptotic covariance matrix of periodic mean.

Usage

```
meanvarcheck(parmodel, n)
```

```
meancovmat(parmodel, n, cor = FALSE, result = "var")
```

Arguments

<code>parmodel</code>	a periodic model.
<code>n</code>	number of observations (TODO: need clarification here).
<code>cor</code>	if TRUE, return correlations
<code>result</code>	if "var", return the diagonal of the covariance matrix, otherwise return the matrix.

Details

Computes asymptotic covariance or correlation matrix of the periodic means.

Value

if result = "var" a matrix, otherwise a vector

modelCycle	<i>Get the cycle of a periodic object</i>
------------	---

Description

Get the cycle of a periodic object, a generic function.

Usage

```
modelCycle(object)

modelCycle(object, ... ) <- value
```

Arguments

object	an object.
value	the new value for the cycle, an object inheriting from "BasicCycle".
...	not used.

Details

modelCycle is essentially internal, for programming. The user level function to get the cycle of an object is [pcCycle](#).

modelCycle returns the Cycle object (in the sense of package **pts**), associated with object. modelCycle is a generic function which makes it possible to associate a cycle with objects from a class, without inheriting from the cycle classes.

By definition, NULL represents the model cycle of objects from classes with no (inherited) method for modelCycle.

The default method of modelCycle returns NULL. The default method for its replacement version throws error.

Value

for modelCycle, an object inheriting from class "BasicCycle" or NULL;

"modelCycle<-" is used for the side effect of changing the cycle of object.

Methods

signature(object = "ANY")

signature(object = "ModelCycleSpec")

ModelCycleSpec-class *Class ModelCycleSpec*

Description

Class ModelCycleSpec.

Objects from the Class

Objects can be created by calls of the form new("ModelCycleSpec", ...).

Slots

Methods

modelCycle signature(object = "ModelCycleSpec"): ...

modelCycle<- signature(object = "ModelCycleSpec"): ...

`nCycles`*Basic information about periodic ts objects*

Description

Basic information about periodic periodic time series objects.

Usage`nCycles(x, ...)``nTicks(x)``nVariables(x, ...)``nSeasons(object)`**Arguments**

`x, object` an object from a periodic time series class.

`...` further arguments for methods.

Details

`nTicks` gives the number of time points, i.e. number of rows in the matrix representation.

`nVariables` gives the number of variables in the time series.

`nSeasons` gives the number of seasons of time series and other periodic objects.

`nCycles` gives the number of cycles available in the data, e.g. number of years for monthly data. It always gives an integer number. Currently, if the result is not an integer an error is raised. **TODO:** There is a case to round up or give the number of full cycles available but this seems somewhat dangerous if done quietly. A good alternative is to provide argument for control of this.

There are further functions to get or set the names of the units of season and the seasons, see [allSeasons](#).

Value

an integer number

five_day_week <- BuiltinCycle(5)
five_day_week
nSeasons(five_day_week)
```

num2pcpar

Fit PAR model using sample autocorrelations

Description

Fit PAR model using sample autocorrelations.

Usage

```
num2pcpar(x, order, result = NULL, ...)
```

Arguments

x	time series, a numeric vector.
order	PAR order, a single number or a vector with one entry for each season.
result	what to return, the default is to return the full model, see Details.
...	passed on to <code>calc_peracf</code> .

Details

Computes the periodic autocorrelations and fits a PAR model using the Periodic Levinson-Durbin algorithm.

The `order` is a vector of non-negative integers, specifying the autoregressive orders for each season. If `order` is a single number, then all seasons have that order.

`mean` controls centering in the computation of the autocorrelations. If `mean` is numeric, then subtract the supplied mean before computing the autocovariances. If `mean` is `TRUE`, the default, compute and subtract the sample periodic mean before computing the autocovariances. If `mean` is `FALSE`, do not centre the series, i.e. assume that the mean is zero.

If `result` is `NULL`, the default, returns the full model. If `result = "coef"`, returns the PAR coefficients only (currently any value of `result` other than `NULL` has this effect).

Value

The coefficients of the fitted model or a list with components:

mean	the mean, set as described in Details.
coef	forward prediction coefficients.
scale	standard deviations of the innovations.

Author(s)

Georgi N. Boshnakov

See Also

pdSafeParOrder(c(3,2,1,2))
pdSafeParOrder(c(3,2,2,1))
num2pcpar(simts1, order = c(3,2,2,1), period = 4 )
num2pcpar(simts1, order = pdSafeParOrder(c(3,2,2,1)), period = 4 )

num2pcpar(simts1, order = c(3,2,1,2), period = 4 )
```

```

num2pcpar(simts1, order = c(3,2,1,2), period = 4, mean = rep(0,4) )
num2pcpar(simts1, order = c(3,2,1,2), period = 4, mean = FALSE )
num2pcpar(simts1, order = c(3,2,1,2), period = 4, mean = FALSE )$coef@m -
      num2pcpar(simts1, order = c(3,2,1,2), period = 4 )$coef@m

## End(Not run)

```

parcovmatlist	<i>Compute asymptotic covariance matrix for PAR model</i>
---------------	---

Description

Compute asymptotic covariance matrix for PAR model

Usage

```
parcovmatlist(parmodel, n, cor = FALSE, result = "list")
```

Arguments

parmodel	PAR model, object of class parModel
n	length of the series or a vector with one element for each season.
cor	If TRUE return correlation matrix.
result	if "list", the default, return a list, if "Matrix" return a Matrix object, otherwise return an ordinary matrix, see Details.

Details

Uses eq. (3.3) in the reference.

If `result = "list"`, `parcovmatlist` returns a list whose s -th element is the covariance matrix of the PAR parameters for the s -th season. Otherwise, if `result = "Matrix"` it returns a block-diagonal matrix created by `.bdiag()` from package "Matrix". If `result = "matrix"` it returns an ordinary matrix (with the current implementation this is returned for any value other than "list" or "Matrix").

Value

a list, matrix or block-diagonal matrix, as described in Details

pc.filter

Applies a periodic ARMA filter to a time series

Description

Filter time series with a periodic arma filter. If `whiten` is FALSE (default) the function applies the given ARMA filter to `eps` (`eps` is often periodic white noise). If `whiten` is TRUE the function applies the "inverse filter" to `x`, effectively computing residuals.

Usage

```
pc.filter(model, x, eps, seasonof1st = 1, from = NA, whiten = FALSE,
          nmean = NULL, nintercept = NULL)
```

Arguments

<code>x</code>	the time series to be filtered, a vector.
<code>eps</code>	residuals, a vector or NULL.
<code>model</code>	the model parameters, a list with components "phi", "theta", "p", "q", "period", "mean" and "intercept", see Details.
<code>seasonof1st</code>	the season of the first observation (i.e., of <code>x[1]</code>).
<code>from</code>	the index from which to start filtering.
<code>whiten</code>	if TRUE use <code>x</code> as input and apply the inverse filter to produce <code>eps</code> ("whiten" <code>x</code>), if FALSE use <code>eps</code> as input and generate <code>x</code> ("colour" <code>eps</code>).
<code>nmean</code>	a vector of means having the length of the series, see Details.
<code>nintercept</code>	a vector of intercepts having the length of the series, see details.

Details

The model is specified by argument `model`, which is a list with the following components:

`phi` the autoregression parameters,

`theta` the moving average parameters,

`p` the autoregression orders, a single number or a vector with one element for each season,

`q` the moving average orders, a single number or a vector with one element for each season,

`period` number of seasons in a cycle,

`mean` means of the seasons,

`intercept` intercepts of the seasons.

The relation between x and eps is assumed to be the following. Let

$$y_t = x_t - mu_t$$

be the mean corrected series, where mu_t is the mean, see below. The equation relating the mean corrected series, $y_t = x_t - \mu_t$, and eps is the following:

$$y_t = c_t + \sum_{i=1}^{p_t} \phi_t(i) y_{t-i} + \sum_{i=1}^{q_t} \theta_t(i) \varepsilon_{t-i} + \varepsilon_t$$

where c_t is the intercept, `nintercept`. The inverse filter is obtained by writing this as an equation expressing ε_t through the remaining quantities.

If `whiten = TRUE`, `pc.filter` uses the above formula to compute the filtered values of x for $t = \text{from}, \dots, n$, i.e. whitening the time series if eps is white noise. If `whiten = FALSE`, eps is computed, i.e. the inverse filter is applied x from eps , i.e. “colouring” x . In both cases the first few values in x and/or eps are used as initial values.

Essentially, the mean is subtracted from the series to obtain the mean-corrected series, say y . Then either y is filtered to obtain eps or the inverse filter is applied to obtain y from eps finally the mean is added back to y and the result returned.

The mean is formed by `model$mean` and argument `nmean`. If `model$mean` is supplied it is recycled periodically to the length of the series x and subtracted from x . If argument `nmean` is supplied, it is subtracted from x . If both `model$mean` and `nmean` are supplied their sum is subtracted from x .

The above gives a vector y , $y_t = x_t - \mu_t$, which is then filtered. If the mean is zero, $y_t = x_t$ in the formulas below.

Finally, the mean is added back, $x_t = y_t + \mu_t$, and the new x is returned.

The above gives a vector y which is used in the filtering. If the mean is zero, $y_t = x_t$ in the formulae below.

`pc.filter` can be used to simulate `pc-arma` series with the default value of `whiten=FALSE`. In this case eps is the input series and y the output.

$$y_t = c_t + \sum_{i=1}^{p_t} \phi_t(i) y_{t-i} + \sum_{i=1}^{q_t} \theta_t(i) \varepsilon_{t-i} + \varepsilon_t$$

Then `model$mean` or `nmean` are added to y to form the output vector x .

Residuals corresponding to a series y can be obtained by setting `whiten=TRUE`. In this case y is the input series. The elements of the output vector eps are calculated by the formula:

$$\varepsilon_t = -c_t - \sum_{i=1}^{q_t} \theta_t(i) \varepsilon_{t-i} - \sum_{i=1}^{p_t} \phi_t(i) y_{t-i} + y_t$$

There is no need in this case to restore x since eps is returned.

In both cases any necessary initial values are assumed to be already in the vectors. If `from` is not supplied it is chosen as the smallest i such that for all $t \geq i$, $t-p[t]>0$ and $t-q[t]>0$, i.e. the filter will not require negative indices for x or eps .

`pc.filter` calls the lower level function `pc.filter.xarma` to do the computation.

Value

The filtered series: the modified x if `whiten=FALSE`, the modified eps if `whiten=TRUE`.

`pc.filter.xarma`

Filter time series with periodic arma filters

Description

Filter time series with periodic arma filters with or options for periodic and non-periodic intercepts.

Usage

```
pc.filter.xarma(x, eps, phi, theta, period, p, q, n, from,
               seasonof1st = 1, intercept = NULL, nintercept = NULL)
```

Arguments

<code>x</code>	the time series to be filtered, a vector.
<code>eps</code>	the innovations, a vector.
<code>phi</code>	the autoregression parameters, a matrix.
<code>theta</code>	the moving average parameters, a matrix.

period	the period (number of seasons in a year).
p	the autoregression orders, recycled to period if length(p)=1.
q	the moving average orders, recycled to period if length(q)=1.
n	a positive integer, the time index of the last observation to be filtered.
from	a positive integer, the time index of the first observation to be filtered.
seasonof1st	a positive integer, the season of the time index of x[1], see Details.
intercept	the intercepts of the seasons, a vector of length period.
nintercept	intercepts, a vector of the same length as x.

Details

pc.filter.xarma is somewhat lower level. The user level function is pc.filter which uses pc.filter.xarma to do the computations.

pc.filter.xarma filters the time series x by the following formula (for t=from, . . . , n):

$$x_t = c_t + \sum_{i=1}^{p_t} \phi_t(i) x_{t-i} + \sum_{i=1}^{q_t} \theta_t(i) \varepsilon_{t-i} + \varepsilon_t,$$

where c_t is the overall intercept at time t , see below. Values of $x[t]$ for t outside the range from, n, if any, are left unchanged. Values for $t < \text{from}$ are used as initial values when needed.

Two intercepts are provided for convenience and some flexibility. The periodic intercept, intercept, is a vector of length period. It is replicated to length n, taking care to ensure that the first element of the resulting vector, say a , starts with intercept[seasonof1st]. nintercept can be an arbitrary vector of length n. It can be used to represent trend or contributions from covariates. nintercept is not necessarily periodic and argument seasonof1st does not affect its use. The overall intercept is obtained as the sum $c = a + \text{nintercept}$.

Usually x is a numeric vector but it can also be a matrix in which each column represents the data for one “year”. Also, the length of x is typically, but not necessarily, equal to n. It is prudent to ensure that length(x) >= n and this must be done if x is a matrix.

Argument phi is ignored if p==0, argument theta is ignored if q==0.

pc.filter.xarma is meant to be called by other functions whose task is to prepare the arguments with proper checks. It does not make much sense to repeat the checks in pc.filter.xarma. In particular, no check is made to ensure that from and n are correctly specified.

This is a low level function meant to be used with basic vectors and matrices. TODO: Implement in C/C++. In the current implementation, it accesses the elements of the arguments with straightforward indexing, so objects from classes may be used as well, provided that $x[t]$, $\text{eps}[t]$, $\text{phi}[t, i]$, $\text{theta}[t, i]$, as well as assignment to $x[t]$, are defined for scalar indices.

Value

Returns x with x[from] to x[n] filled with the filtered values and values outside the interval from, . . . , n left unchanged.

The mode of x is left unchanged. In particular, x may be a matrix with each row representing the data for a season. This is convenient since periodic time series are often more easily processed in this form.

`pc.hat.h`*function to compute estimates of the h weights*

Description

The h coefficients are scaled cross-covariances between the time series and the innovations. This function computes estimates for h using as input the observed series, a series of estimated innovations, and an estimate of the variance of the innovations.

Usage`pc.hat.h(x, eps, maxlag, si2hat)`**Arguments**

x	the observed time series $x(t)$
eps	a series of estimated innovations
maxlag	maximum lag
si2hat	estimate of the variance of the innovations

Details

If missing, the variance of the innovations is estimated from eps.

Value

A matrix of the coefficient up to lag maxlag with one row for each season.

pcacfMat

*Compute PAR autocovariance matrix***Description**

Compute PAR autocovariance matrix

Usage

```
pc.acf.parModel(parmodel, maxlag = NULL)
```

```
pcacfMat(parmodel)
```

Arguments

parmodel	PAR model, an object of class parModel.
maxlag	maximum lag

Details

`pc.acf.parModel` returns the autocovariances of a PAR model in season-lag form with maximum lag equal to `maxlag`. If `maxlag` is larger than the available precomputed autocovariances, they missing ones are computed using the Yule-Walker relations. Note that `pc.acf.parModel` assumes that there are enough precomputed autocovariances to use the Yule-Walker recursions directly.

TODO: `pc.acf.parModel` is tied to the old classes since it accesses their slots. Could be used as a template to streamline the method for autocovariances for class "PeriodicAutocovariance".

The season-lag form can be easily converted to other forms with the powerful indexing operator, see the examples and [slMatrix-class](#).

`pcacfMat` is a convenience function for statistical inference. It creates a covariance matrix with dimension chosen automatically. This covariance matrix is such that the asymptotic covariance matrix of the estimated parameters can be obtained by dividing sub-blocks by innovation variances and inverting them. See, eq. (3.3) in the reference.

Value

for `pcacfMat`, a matrix

for `pc.acf.parModel`, an `slMatrix`

```

pcacf_pwn_var

Variances of sample periodic autocorrelations

Description

Computes the variances of sample periodic autocorrelations from periodic white noise.

Usage

```
pcacf_pwn_var(nepoch, period, lag, season)
```

Arguments

lag	desired lags, a vector of positive integers.
season	desired seasons.
nepoch	number of epochs.
period	number of seasons.

Details

These are given by McLeod (1994), see the reference, eq. (4.3).

Value

A matrix whose (i,j)th entry contains the variance of the autocorrelation coefficient for season `season[i]` and lag `lag[j]`.

pcalg1

Periodic Levinson-Durbin algorithm

Description

Calculate partial periodic autocorrelations, forward and backward prediction coefficients and error variances using the periodic Levinson-Durbin algorithm.

Usage

```
alg1(r, p)
```

Arguments

r periodic autocovariances, a matrix, see ‘Details’.
p autoregressive orders, numeric vector.

Details

`alg1(r, p)` calculates the partial periodic correlations from autocovariances r and autoregression orders p . The matrix r has the same format as that of the r slot of `pcAcvf` objects. The periodicity, d , is set equal to the number of rows in r . If the length of p is not equal to the periodicity, all autoregressive orders are set to the first element of p . This last feature is really meant to be used only with a scalar p .

The convention for the signs of the coefficients is the one from Boshnakov(1996) and is consistent with other R time series functions.

`pmax` below stands for the maximal element of p , i.e. the maximal AR order.

As in the non-periodic case, the periodic Levinson-Durbin algorithm fits recursively models of order $0, 1, \dots, pmax$. Namely, at step i the AR orders for all seasons are set to i . This is done in a way that correctly handles the case when not all elements of p are equal, see the references.

The essential quantities calculated by the periodic Levinson-Durbin algorithm are returned as matrices, whose i th rows contain values for season i . The complete details depend on the quantities, as described below.

The partial autocorrelations, the forward innovation variances and the backward innovation variances are returned as matrices with d rows and $1+pmax$ columns, whose j -th columns contain the quantities for order $j-1$ (partial autocorrelations, forward innovation variances and backward innovation variances, respectively). Note that the lag-0 partial autocorrelations are the autocovariances for lag 0, see the references for details.

The forward autoregression parameters are returned as a list whose j th element is a matrix containing the coefficients for order j . Similarly for the backward autoregression parameters.

One often is interested in the model of order p only. Its coefficients are given by `af[[pmax]]`, while the innovation variances are in the last column of `fv`.

Value

A list with the following elements.

<code>orders</code>	autoregression orders
<code>be</code>	partial autocorrelations, a matrix with d rows
<code>fv</code>	forward innovation variances, a matrix with d rows
<code>bv</code>	backward innovation variances, a matrix with d rows
<code>af</code>	forward autoregression parameters, a list with one element for the parameters for each order.
<code>ab</code>	backward autoregression parameters, a list with one element for the parameters for each order.

Note

The autoregression orders of the output are not necessarily the same as those specified in the call. There may be no PAR model with the requested orders, see the references.

pcalg1util

Give partial periodic autocorrelations or other partial prediction quantities for a pcAcvf object.

Description

Give partial periodic autocorrelations or other partial prediction quantities for a pcAcvf object.

Usage

```
alg1util(x, s, at0 = 1)
```

Arguments

x	an object of a class inheriting from <code>pc.Model.WeaklyStat</code>
s	the required quantity, the name of one of the elements of the list returned by <code>alg1</code> .
at0	if not identical to "var", replace the elements of the result at lag zero with 1, see 'Details'.

Details

This function is a wrapper for `alg1()`. It calls `alg1`, to do the computations and returns the requested element as an object from class `s1Matrix`. The model order is set to the maximal lag available in x ,

If `at0` is the character string "var", then the lag zero values in the result are set to the lag zero autocovariances, otherwise they are set to 1. This is mainly relevant for the periodic partial autocorrelations (`s="be"`), since the setting `at0="var"` ensures that they are in one to one correspondence with the autocovariances.

Value

the requested quantity as an object of type `s1Matrix`

pcApply-methods

Apply a function to each season

Description

Apply a function to each season.

Usage

```
pcApply(object, ...)

## S4 method for signature 'numeric'
pcApply(object, nseasons, FUN, ...)

## S4 method for signature 'matrix'
pcApply(object, nseasons, FUN, ...)

## S4 method for signature 'PeriodicTS'
pcApply(object, FUN, ...)

## S4 method for signature 'PeriodicMTS'
pcApply(object, FUN, ...)
```

Arguments

object	an object for which periodic mean makes sense.
nseasons	number of seasons.
FUN	a function, as for apply .
...	further arguments for FUN.

Details

For univariate periodic time series, `pcApply` applies `FUN` to the data for each season. For multivariate periodic time series, this is done for each variable.

The methods for "numeric" and "matrix" are equivalent to those for "PeriodicTS" and "PeriodicMTS", respectively. The difference is that the latter two don't need argument `nseasons` and take the names of the seasons from `object`.

Argument "..." is for further arguments to `FUN`. In particular, with many standard R functions argument `na.rm = TRUE` can be used to omit NA's, see the examples.

In the univariate case, when `length(object)` is an integer multiple of the number of seasons the periodic mean is equivalent to `apply(matrix(object, nrow = nseasons), 1, FUN, ...)`.

Value

numeric or matrix for the methods described here, see section `Details`.

`pcAR2acf`*Compute periodic autocorrelations from PAR coefficients*

Description

Compute periodic autocorrelations from PAR coefficients. This effectively solves the inverse problem to that solved by the periodic Levinson-Durbin algorithm but does not use a recursion.

Usage

```
pcAR2acf(coef, sigma2, p, maxlag = 10)
```

Arguments

<code>coef</code>	PAR coefficients, a matrix, see Details.
<code>sigma2</code>	innovations variances.
<code>p</code>	PAR order.
<code>maxlag</code>	How many lags to compute.

Details

`coef` is a matrix with the coefficients for season i in the i -th row. The coefficients start from lag 1. The first few autocorrelations are computed by solving a linear system, see the references. The rest, are generated using the periodic Yule-Walker equations.

Value

a matrix, in which row s contains the acf's for season s for lags 0, 1, ..., `maxlag` (in this order).

pcarma_solve

Functions to compute various characteristics of a PCARMA model

Description

Given a PCARMA model, create a function for computing autocovariances or coefficients of the corresponding infinite moving average representation or prepare the linear system whose solution provides the first few autocovariances of the model.

Usage

```
pcarma_acvf_lazy(phi, theta, sigma2, p, q, period, maxlag = 100)
pcarma_h_lazy(phi, theta, p, q, period, maxlag = 200)
pcarma_acvf_system(phi, theta, sigma2, p, q, period)
pcarma_param_system(acf, h, sigma2, p, q, period)
pcarma_h(h, na = NA)
```

Arguments

phi	the autoregression parameters, an object of class "slMatrix"
theta	the moving average parameters, an object of class "slMatrix"
sigma2	the innovation variances, an object of class "PeriodicVector" or a vector of size period, Details.
p	the (maximal) autoregression order or the autoregression orders.
q	the (maximal) moving average order or the moving average orders.

period	number of seasons in an epoch
maxlag	maximal lag for which the result is stored internally.
acf	the autocovariance function, an object of class pcAcvf, slMatrix, or similar
h	pcarma_param_system, $h(t, k)$ is expected to return the coefficient $h_{t,k}$. h is usually created by <code>pcarma_h_lazy</code> . For <code>pcarma_h</code> , a matrix of $h(t, i)$ coefficients.
na	not used currently, controls what to do for large lags.

Details

Compute acvf from parameters:

`pcarma_acvf_lazy` creates a function that will compute (on demand) values of the acf by a recursive formula. Computed values are stored internally for lags up to `maxlag`.

System for acvf from parameters:

`pcarma_acvf_system` forms a linear system for the calculation of autocovariances from the parameters of a pc-arma model. The argument `theta` is not used if $q = 0$ and `phi` is not used if $p = 0$.

System for parameters from acvf: `pcarma_param_system` takes the periodic autocovariances of a pc-arma model and computes a matrix and a vector representing the linear system whose solution provides the parameters of the model.

Scalar `p` specifies the same autoregression order for each season, similarly for `q`. `p` and `q` may be vectors of length `period` specifying the order for each season individually. In the latter case the solution of the system may not be a proper model or, if it is, its autocovariances may not be the ones used here! See the references for details.

The class of `acf` is not required to be one of those explicitly listed above, but it should understand their indexing conventions, similarly for `sigma2`.

For pure autoregression, $q = 0$, the arguments `h` and `sigma2` are ignored. **TODO: add sigma2 (if supplied) to the returned list?**

Compute h from parameters:

`pcarma_h_lazy`: $h(t, i)$ are the coefficients in infinite the moving average representation of the pc.arma model. The calculations use formula (4.4) from my paper (or elsewhere) with internal storage (in an `slMatrix`) of calculated results (for $i < \text{maxlag}$) and recursive calls to itself. So, it is not necessary to compute $h(t, i)$ in any particular order.

Infinite MA coefficients(h):

`pcarma_h` Function to create a function for lazy computation of $h(t, i)$ in pc.arma models

Takes a matrix of $h(t, i)$ coefficients and returns a function that calculates $h(t, i)$ from my paper xxx. The returned value can be used in the same way as that of `pcarma_h_lazy`.

Value

for `pcarma_acvf_lazy`:

a function taking two arguments `t` and `k` such that for scalar `t` and `k` the call `f(t, k)` will return $EX(t)X(t-k)$. If either of the arguments is a vector, then `f(t, k)` returns a matrix of size $(\text{length}(t), \text{length}(k))$ containing the respective autocovariances.

for pcarma_h_lazy:

a function, say h. In calls to h, if both arguments are scalars $h(t, i)$ returns $h_{t,i}$. If at least one of the arguments is a vector a matrix of values of h is returned.

for pcarma_acvf_system:

a list with two components representing the linear system:

A The $(p + 1)$ period \times $(p + 1)$ period matrix of the system, an object of class "matrix".

b The right-hand side of the system, a vector of length $(p + 1)$ period, an object of class "vector".

$A^{-1}b$ can be used to get a vector of the autocovariances in the following order (d is the period, p is the maximal AR order):

$$K(1, 0), \dots, K(d, 0), K(1, 1), \dots, K(d, 1), \dots, K(1, p), \dots, K(d, p).$$

for pcarma_param_system:

A list with components representing the linear system and the AR and MA orders:

A The matrix of the system

b The right-hand side of the system

p The AR order

q The MA order

$A^{-1}b$ will return a vector of the parameters of the pc-arma model: all parameters for the first season, followed by all parameters for the second seasons and so on. For each season the parameters are in the following order (s is the current season, d is the period, $p[s]$ and $q[s]$ are the corresponding AR and MA orders):

$$\sigma^2(s), \phi(s, 1), \dots, \phi(s, p[s]), \theta(s, 1), \dots, \theta(s, q[s]).$$

for pcarma_h:

a function, say h. In calls to h, if both arguments are scalars $h(t, i)$ returns $h_{t,i}$. If at least one of the arguments is a vector a matrix of values of h is returned. Analogous to pcarma_h_lazy.

Note

for pcarma_acvf_lazy: The recursion may become extremely slow for lags greater than maxlag. If large lags are likely to be needed the argument maxlag should be used to increase the internal storage. The default for maxlag currently is 100.

pcarma_unvec

Functions for work with a simple list specification of pcarma models

Description

Handle a simple list specification of pcarma models. Functions to convert to and from a representation appropriate for handing on to optimisation functions.

Usage

```
pcarma_prepare(model, type)
pcarma_unvec(model)
pcarma_tovec(model)
```

Arguments

model	specification of a pcarma model, a list, see Details.
type	not used.

Details

These functions work with a specification of a pcarma model as a list with components `period`, `p`, `q`, `param`, `phi`, `theta` and `si2`, see also section ‘Values’. The functions do not necessarily need or examine all these components.

Argument `model` is a list with components as accepted by `pcarma_prepare`. Details are below but the guiding rule is that there are sensible defaults for absent components.

`pcarma_prepare` gives a standard representation of `model`, in the sense that it ensures that the model has components `period`, `p` and `q`, such that `p` and `q` are vectors of length `period`. `pcarma_prepare` does not examine any other components of the model. (**TODO:** do the same for the innovation variance?)

If `model$period` is `NULL`, `pcarma_prepare` sets it to the length of the longer of `model$p` and `model$q`. If `model$p` is a scalar it is extended with `rep(model$p, period)`. Missing or `NULL` `model$p` is equivalent to `model$p = 0`. `model$q` is processed analogously.

The net effect is that `period`, `p` and `q` will be set as expected as long as `period` is given or at least one of the other two is of length equal to the period. A warning is issued if `period <= 1` (it is all too easy to give scalar values for `p` and `q` and forget to set the period, in which case `period` will be deduced to be one).

A number of functions (including `pcarma_tovec` and `pcarma_unvec`) dealing with the list representation of pcarma models start by calling `pcarma_prepare` to avoid the need for handling all possible cases.

`pcarma_tovec` returns a list with components `p`, `q` and `param`, where `param` is a numeric vector containing the pcarma parameters and the innovations variances and thus is suitable for optimisation functions. Notice that it is component `param` that is a vector. The reason that `pcarma_tovec` returns a list, is that the caller may need to do further work before calling a generic optimisation function. For example, it may wish to drop the variances from the vector.

`pcarma_unvec(model)` performs the inverse operation. It takes a list like that produced by `pcarma_tovec` and converts it to a detailed list containing the components of the model.

Value

for `pcarma_unvec`, a list with components:

<code>p</code>	autoregressive orders, numeric vector
<code>q</code>	moving average orders, numeric vector
<code>si2</code>	innovation variances

phi autoregressive parameters
 theta moving average parameters
 for pcarma_tovec, a list with components:
 p autoregressive order
 q moving average order
 param parameters of the model, a numeric vector. TODO: give the order of the parameters in the vector!
 for pcarma_prepare, a list as pcarma_unvec, see also Details.

Note

The specification and the functions were created ad hoc to get the computations going and are not always consistent with other parts of the package.

pcCycle-methods *Create or extract Cycle objects*

Description

pcCycle() is a generic function with methods for creating, converting, modifying, and extracting cycle objects. BuiltinCycle() is a function to create cycle objects from the builtin cycle classes.

Usage

```
pcCycle(x, type, ...)
```

```
BuiltinCycle(n, coerce = FALSE, first = 1, stop = TRUE)
```

Arguments

x an object, methods include numeric, character and cyclic objects, see Details.
 type class of the result. If equal to "auto", the default, the class is determined by the argument(s), otherwise should be the name of a cycle class.
 ... further arguments for methods.
 n number of seasons, an integer.
 coerce if TRUE coerce the objects to a modifiable cycle class, currently "SimpleCycle".
 first which season is first for this object.
 stop if TRUE, the default, throw error if there is no builtin class with n seasons, otherwise create a "BareCycle" object.

Details

pcCycle serves as both a constructor and extractor of cycle objects. It is meant to just do the right thing, relieving the user from the burden of specifying a particular cycle class.

If *x* is numeric it constructs a cycle object with period *x* and additional properties as specified by the other arguments. If *x* is a character string, it is taken to be the name of one of the builtin cycles.

pcCycle can be used to create a modified version of a cycle object and/or convert it to another cycle type. This is done by providing a cycle object as argument *x*, i.e. one inheriting from "BasicCycle".

If *x* inherits from "Cyclic", pcCycle returns its cycle component.

Argument *type* should be rarely needed, except maybe to conveniently force conversion of the builtin type to an ordinary type.

The descriptions of the individual methods in section Methods give some further specific details.

BuiltinCycle is a convenience function to create objects from builtin cycle classes by specifying the number of seasons. The builtin cycle classes are essentially fixed, except that which season is considered first can be changed using argument *first*. If other modifications are desired, convert the returned builtin cycle object to class "SimpleCycle". This can be done also in the call to BuiltinCycle() by specifying *coerce = TRUE*.

By default, BuiltinCycle throws an error if there is no builtin class with the requested number of seasons. Set argument *stop* to FALSE to create an object from class "BareCycle" instead (and it will be converted to "SimpleCycle" if *coerce = TRUE*). Argument *stop* is mainly for programming.

Value

for pcCycle, an object from one of the cycle classes;

for BuiltinCycle, an object from one of the builtin classes, coerced if requested.

Methods

signature(*x* = "numeric", *type* = "missing") creates a cycle object with period *x*. If *x* is the only argument, a "BareCycle" object is created, otherwise the constructor of "SimpleCycle" is invoked with all arguments except *type* passed on to it.

signature(*x* = "character", *type* = "missing") creates an object from the class specified by *x*. Currently this is equivalent to new(*x*, ...) but somewhat more portable. Future amendments may use a more suitable class for some combinations of the arguments. Also, if a class is renamed, a code will be inserted here to create an equivalent object.

signature(*x* = "numeric", *type* = "character")

signature(*x* = "character", *type* = "character") first call the method with *type* = "missing", then convert the result to class *type*.

signature(*x* = "Cyclic", *type* = "ANY") extracts the cycle component of *x* (x@cycle). Currently ignores the remaining arguments.

signature(*x* = "BasicCycle", *type* = "missing") convert an object from any cycle class to class "SimpleCycle". This is like as(*x*, "SimpleCycle") but can have further arguments.

signature(*x* = "BasicCycle", *type* = "character") convert an object from any cycle class to class *type*.

```
signature(x = "ts", type = "missing")
signature(x = "ts", type = "character") when x is of class "ts", extract the frequency and
convert it to a cycle class. Just as for "ts", certain frequencies are taken to correspond to
specific classes. While base R treats periodicities 4 and 12 specially, pcCycle extends this to
all builtin classes in pcts. Argument type can be used to overwrite this default behaviour by
requesting a specific class. In particular, type = "BareCycle" and type = "" cause the result
to be "BareCycle".
signature(x = "PeriodicTimeSeries", type = "missing")
signature(x = "PeriodicTimeSeries", type = "character") extract the cycle part of an ob-
ject inheriting from "PeriodicTimeSeries", currently "PeriodicTS" or "PeriodicMTS".
Argument type can be used to force the result to be from a specific cycle class, as in the
methods for "ts".
```

BuiltinCycle(19, coerce = TRUE, stop = FALSE)
```

pclsdf

*Fit PAR models using least squares***Description**

Fit PAR models using least squares. The model may contain intercepts and linear trends, seasonal or non-seasonal.

Usage

```
pclsdf(x, d, lags = integer(0), sintercept = TRUE, sslope = FALSE,
       intercept = FALSE, slope = FALSE, xreg, contrasts = NULL,
       seasonof1st = NULL, coefonly = FALSE)
```

Arguments

x	time series, a numeric vector.
d	period, an integer.
lags	an integer vector, typically 1:p, where p is the order of the autoregression. The same lags are used for all seasons.
sintercept	if TRUE include seasonal intercepts.
sslope	if TRUE include seasonal linear trend.
intercept	if TRUE include non-seasonal intercept.
slope	if TRUE include non-seasonal linear trend.
xreg	additional regressors, not used currently.
contrasts	contrasts to use for the seasons factor variable.
seasonof1st	season of the first observation in the time series, see Details.
coefonly	if TRUE, return only the parameters of the fitted model, otherwise include also the object returned by lm.

Details

This function fits PAR models by the method of least squares. Seasonal intercepts are included by default. Non-seasonal intercepts are available, as well as seasonal and non-seasonal linear trend. Separate arguments are provided, so that any combination of seasonal and non-seasonal intercepts and slopes can be specified.

If `coefonly` is TRUE, `pclsdf` returns only the estimated parameters, otherwise it includes additional statistical information, see section Note for the current details.

Value

A list with the components listed below. Some components are present only if included in the model specification.

<code>par</code>	the PAR coefficients, a matrix with a row for each season.
<code>sintercept</code>	(if specified) seasonal intercepts, a numeric vector.
<code>sigma2hat</code>	innovation variances.
<code>formula.char</code>	the formula used in the call of <code>lm</code> , a character string.
<code>fit</code>	(if <code>coefonly = FALSE</code>) the fitted object obtained from <code>lm</code> .

Note

Currently, `pclsdf` prepares a model formula according to the specification and calls `lm` to do the fitting. Component "fit" in the result (available when `coefonly = FALSE`) contains the raw fitted object returned by `lm`. Statistical inference based on this object would, in general, not be justified for correlated data.

todo: currently some of the parameters are returned only via the fitted object from `lm`.

```

pclspiar

Fit a periodically integrated autoregressive model

Description

Fit a periodically integrated autoregressive model.

Usage

```
pclspiar(x, d, p, icoef = NULL, parcoef = NULL, sintercept = FALSE,
         seasonof1st = 1, weights = TRUE, itol = 1e-07, maxniter = 1000)
```

Arguments

x	time series.
d	period.
p	order of the model, a positive integer, see Details.
icoef	initial values for the periodic integration coefficients. If missing or NULL suitable values are computed.
parcoef	not used currently.
sintercept	if TRUE include seasonal intercepts.
seasonof1st	season of the first observation.
weights	if TRUE, use periodic weights in the nonlinear least squares, see Details.
itol	threshold value for the stopping criterion.
maxniter	maximum number of iterations.

Details

This function fits a periodically integrated autoregressive model using non-linear least squares. The order of integration is one and the order of the periodically correlated part is $p - 1$. So, p must be greater than or equal to one.

If `weights = TRUE` the non-linear optimisation is done with weights inversely proportional to the innovation variances for the seasons, otherwise the unweighted sum of squared residuals is minimised.

Value

a list currently containing the following elements:

icoef	coefficients of the periodic integration filter.
parcoef	coefficients of the PAR filter.
sintercept	seasonal intercepts.
sigma2hat	innovation variances.

pcMean-methods

Compute periodic mean

Description

Compute periodic mean, generic function.

Usage

```
pcMean(object, ...)
```

S4 method for signature 'numeric'

```
pcMean(object, nseasons, ...)
```

S4 method for signature 'matrix'

```
pcMean(object, nseasons, ...)
```

S4 method for signature 'PeriodicTS'

```
pcMean(object, ...)
```

S4 method for signature 'PeriodicMTS'

```
pcMean(object, ...)
```

Arguments

object an object for which periodic mean makes sense.
 nseasons number of seasons.
 ... further arguments for methods.

Details

For univariate periodic time series, pcMean computes the mean for each season and returns a named vector. For multivariate periodic time series, the result is a matrix with one column for each variable.

The methods for "numeric" and "matrix" are equivalent to those for "PeriodicTS" and "PeriodicMTS", respectively. The difference is that the latter two don't need argument nseasons and take the names of the seasons from object.

Argument na.rm = TRUE can be used to omit NA's.

In the univariate case, when length(object) is an integer multiple of the number of seasons the periodic mean is equivalent to computing the row means of matrix(object, nrow = nseasons).

Value

numeric or matrix for the methods described here, see section 'Details'.

Methods

```
signature(object = "matrix")
signature(object = "numeric")
signature(object = "PeriodicMTS")
signature(object = "PeriodicTS")
signature(object = "VirtualPeriodicArmaModel")
```

pcTest-methods

Test for periodicity

Description

Test for periodicity

Usage

```
pcTest(x, nullmodel, nseasons, ...)
```

Arguments

x	the object to be tested, e.g. a time series or a periodic acf
nullmodel	specification of the test to be performed
nseasons	number of seasons
...	additional arguments to be passed on to methods

Details

This is a generic function which acts as a dispatcher for various tests for periodicity and periodic correlation.

x is typically a time series but conceptually it is an object containing the statistics needed for carrying out the requested test. For example, x may be the periodic autocovariance function for tests based on sample autocorrelations and autocovariances.

The method with signature (x = "ANY", nullmodel = "character") may be considered as default for pcTest. The "real" default method simply prints an error message.

Value

a list containing the results of the requested test, see the individual methods for details

Methods

signature(x = "ANY", nullmodel = "character") Argument nullmodel specifies the test to be performed. It should be a single character string. If it is one of the strings recognised by this method, the test specified below is carried out. Otherwise nullmodel is taken to be the name of a function which is called with arguments (x, ...).

Currently, the following character strings are recognised:

"wn" Box test for (non-periodic) white noise, simply calls `Box.test`.

"piar" Franses (1996) test for periodic integration.

signature(x = "slMatrix", nullmodel = "character") x here is the periodic autocovariance function. This method works similarly to the method for signature (x = "ANY", nullmodel = "character"), see its description.

Currently, the following character strings are recognised:

"pwn" Ljung-Box test for periodic white noise,
"periodicity" McLeod test for periodic correlation.
signature(x = "numeric", nullmodel = "character")
signature(x = "PeriodicTimeSeries", nullmodel = "character")

Note

TODO: critical values

pcTest(cu, "piar", 4, 1, sintercept = TRUE)

if(require(partsm)){
# same with LRurpar.test from partsm
LRurpar.test(cu, list(regular = c(0,0,0), seasonal = c(1,0), regvar = 0), p = 1)
}
```

Pctime

Convert between Pctime and datetime objects

Description

Class "Pctime" is an S3 class inheriting from the base R datetime class "POSIXct". It has methods for conversion between datetimes and the pcts cycle-season pairs, as well as convenience methods for a few other functions.

Usage

```
Pctime(x, cycle, ...)

as_Pctime(x, ...)

## S3 method for class 'Pctime'
x[i, j, drop = TRUE]
```

```
## S3 method for class 'Pctime'
x[ [..., drop = TRUE]]

## S3 method for class 'Cyclic'
as_Pctime(x, ...)

## S3 method for class 'PeriodicTimeSeries'
as_Pctime(x, ...)
```

Arguments

x	for Pctime, numeric vector, matrix with two columns, or any object that is or can be converted to datetime. For the other functions see Details.
cycle	a positive integer, cycle object, or missing.
i	subscript
j	not used
drop	not used
...	further argument for methods.

Details

Pctime represents periodic times with cycle specification contained in attribute "cycle". It is basically datetime (inheriting from "POSIXct") with additional attribute(s).

For printing Pctime objects are shown as cycle-season pairs. To print in other formats, just convert them using `as_datetime` or other suitable function. Note though that some cycles in pcts do not have natural datetime representation. For them, Pctime sets it arbitrarily as the number of seconds from a origin.

The seasons in cycle-season pairs are numbered from one to the number of seasons. Names and abbreviations are used when available and this is the case for all builtin cycles and partial cycles obtained from them.

The cycles in cycle-season pairs are numbered from a starting point. For years, it is what is expected. For cycles representing weeks, week 1 is the first ISO week of 1970, so `c(1,1)` corresponds to 1969-12-29. For some other cycle classes `c(1,1)` also corresponds to the first time in the first ISO week of 1970.

Subsetting with "`[`" keeps the Pctime class, while "`[[`" returns a datetime object. Other standard functions work with Pctime objects, as well, including `seq`.

A common source of frustration is the accidental use of `as.Date` or `as_date`, instead of `as.POSIXlt` or `as_datetime`. These four are often equivalent, most notably for monthly, quarterly and daily observations but, in general, conversion to dates drops the fractional day part of a datetime.

The default time zone is UTC. Other time zones can be used since the calculations use standard datetime and date functions from base R and package `lubridate` (Grolemund and Wickham 2011), but currently this has not been tested.

Value

for Pctime, an object from S3 class Pctime

References

Grolemund G, Wickham H (2011). “Dates and Times Made Easy with lubridate.” *Journal of Statistical Software*, **40**(3), 1–25. doi:10.18637/jss.v040.i03.

Examples

```
## a bare bone date for four seasons
pct4 <- Pctime(c(2020, 2), pcCycle(4))
pct4

pcts

Create objects from periodic time series classes

Description

Create objects from periodic time series classes.

Usage

```
pcts(x, nseasons, start, ..., keep = FALSE)
```

Arguments

x	a time series.
nseasons	number of seasons. This argument is ignored by some methods.
start	the starting time of the time series, can be a (cycle, season) pair or any object that can be converted to datetime.
keep	if TRUE and x is from class "ts", "mts", "zoo", or "zooreg", create a periodic object inheriting from that class.
...	further arguments to be passed on to methods.

Details

pcts creates periodic time series objects inheriting from "PeriodicTimeSeries". The particular class depends on arguments x and, in some cases, keep. The idea is that in normal use the user does not care about the particular class. See section 'Methods' for further details.

Familiar functions from base-R work with the objects created by pcts. The help page [window](#) describes such methods and gives examples.

There are also methods for as for conversion to and from the time series classes defined in package **pcts**.

Value

an object inheriting from "PeriodicTimeSeries", the defaults are "PeriodicTS" for univariate and "PeriodicMTS" and for multivariate time series.

Methods

```
signature(x = "numeric", nseasons = "missing")
signature(x = "numeric", nseasons = "numeric")
signature(x = "numeric", nseasons = "BasicCycle") Creates an object of class "PeriodicTS",
  the native class for univariate periodic time series in package "pcts".
signature(x = "matrix", nseasons = "missing")
signature(x = "matrix", nseasons = "numeric")
signature(x = "matrix", nseasons = "BasicCycle") Creates an object of class "PeriodicMTS",
  the native class for multivariate periodic time series in package "pcts".
signature(x = "data.frame", nseasons = "ANY") Currently this just converts x to matrix and
  calls pcts recursively. See the methods with x = "matrix" in the signature.
signature(x = "ts", nseasons = "missing")
signature(x = "ts", nseasons = "numeric") If keep = TRUE creates an object of class "PeriodicTS_ts",
  otherwise the result is from "PeriodicTS". The number of seasons is taken from the "mts"
  object.
signature(x = "mts", nseasons = "missing")
signature(x = "mts", nseasons = "numeric") If keep = TRUE creates an object of class "PeriodicMTS_ts",
  otherwise the result is from "PeriodicMTS". The number of seasons is taken from the "ts"
  object.
signature(x = "xtsORzoo", nseasons = "missing") x needs to be a regular time series, pos-
  sibly with missing values for some times (technically, zoo::is.regular(x) should give
  TRUE). For daily time series, the cycle is taken to be day of week or a subcycle of it, most
  commonly Monday-Friday. The implementation of this method is incomplete but for daily
  data should work as described.
```

Examples

```
## convert a ts object, no need for further info
pcts(AirPassengers, 12)

## numeric
v24 <- rnorm(24)
```

```

pcts(v24, nseasons = 4)          # generic seasons
pcts(v24, nseasons = BuiltinCycle(4)) # Quarter/Year
ts1 <- pcts(v24, nseasons = BuiltinCycle(4), c(2006, 1)) # Quarter/Year with dates

## select subset of the seasons
window(ts1, seasons = 3:4)

## matrix, multivariate pcts
m24 <- matrix(v24, ncol = 3)
colnames(m24) <- c("A", "B", "C")
pcts(m24, nseasons = 4)          # generic seasons
pcts(m24, nseasons = BuiltinCycle(4)) # Quarter/Year
mts1 <- pcts(m24, nseasons = BuiltinCycle(4), c(2006, 1)) # Quarter/Year with dates
mts1

## select subset of the seasons for mutivariate
window(mts1, seasons = 3:4)

```

pcts-deprecated *Deprecated Functions and classes in Package **pcts***

Description

These functions and classes are marked for removal and are provided temporarily for compatibility with older versions of package **pcts** only. Use the recommended renamed or new functions instead.

Class "FiveDayWeekCycle" is deprecated, use `BuiltinCycle(5)` to create objects with equivalent functionality, see [BuiltinCycle](#).

Details

mCpar has been renamed to `sim_parCoef`

sim_arAcf has been renamed to `sim_parAcvf`

pcts_exdata *Periodic time series objects for examples*

Description

Periodic time series objects for examples and tests. These objects are from classes defined in package "pcts" and as a consequence are not suitable for access with `data()`.

Usage

```
pcts_exdata(x, envir = parent.frame())
```

Arguments

x	a character vector giving the names of objects. If missing, all available objects will be created. Can also be NA. In that case no objects are created and the names of all available objects are returned.
envir	environment where the objects are put, the default is the environment of the caller.

Details

The requested objects are created and put in `envir`. Its default is the environment of the caller, which should be sufficient in most use cases.

The following objects are currently available: `ap`, `ap7to9`, `pcfr`, `pcfr2to4`.

Value

if `x` is NA, the names of the available objects. Otherwise the function is called for the side effect of creating objects in `envir` and the return value (the names of the created objects) is usually discarded.

See Also

[dataFranses1996](#)

Examples

```
## the objects are created with something like:
ap <- pcts(AirPassengers)
ap7to9 <- window(ap, seasons = 7:9)

pcfr <- pcts(dataFranses1996)
pcfr2to4 <- pcfr[2:4]
```

pc_sdfactor

Compute normalising factors

Description

Compute a matrix of factors such that elementwise division of the periodic autocovariance matrix by it will give the periodic autocorrelations.

Usage

```
pc_sdfactor(sd, maxlag)
```

Arguments

sd	standard deviations of the seasons numeric.
maxlag	maximal lag, a number.

Value

a matrix of coefficients of size `period x (maxlag+1)`. The length of `sd` is taken to be the period.

Author(s)

Georgi N. Boshnakov

See Also

[autocorrelations](#)

Examples

```
## equivalent to data(Fraser, package = "pear")
Fraser <- window(Fraser2017, start = c(1912, 3), end = c(1990, 12))

logfraser <- window(pcts(log(Fraser)), start = c(1913, 1))
acvf1 <- autocovariances(logfraser, maxlag = 2)
fac <- pc_sdfactor(sqrt(acvf1[, 0]), 2)
fac[, 1:3]

acrf1 <- autocorrelations(logfraser, maxlag = 2)
all.equal(acvf1[, ], acrf1[, ] * fac) # TRUE
```

pdSafeParOrder

Functions for some basic operations with seasons

Description

Functions for some basic operations with seasons.

Usage

```
pdSafeParOrder(p)
```

Arguments

`p` autoregression order, a vector of integers.

Details

`pdSafeParOrder(p)` modifies the periodic AR order specified by vector `p`. The modified order is such that the correspondence between autocovariances and partial autocorrelations is one-to-one, see the references for details.

Value

a vector of integers

 PeriodicArModel-methods

Create objects from class PeriodicArModel

Description

Create objects from class PeriodicArModel

Usage

```
PeriodicArModel(object, ...)
```

Arguments

object an object, can have one of a number of classes.
... further arguments for methods.

Details

PeriodicArModel creates objects from class PeriodicArModel. This is a generic function with dispatch methods on the first argument.

Value

an object from class "PeriodicArModel"

Methods

signature(object = "matrix") "object" gives the coefficients, one row per season.

signature(object = "numeric") "object" gives the model order. Its length is taken to be the number of seasons. The coefficients are set to NA.

signature(object = "PeriodicMonicFilterSpec")

signature(object = "VirtualPeriodicArmaModel")

signature(object = "PeriodicMonicFilterSpec")

signature(object = "VirtualPeriodicArmaModel")

PeriodicAutocorrelations-class

Class PeriodicAutocorrelations

Description

Class PeriodicAutocorrelations.

Objects from the Class

Objects can be created by calls of the form `new("PeriodicAutocorrelations", ..., data)`.

Slots

modelCycle: Object of class "BasicCycle" ~~

data: Object of class "Lagged" ~~

Extends

Class "ModelCycleSpec", directly. Class "FlexibleLagged", directly. Class "VirtualPeriodicAutocorrelations", directly. Class "Lagged", by class "FlexibleLagged", distance 2. Class "VirtualPeriodicModel", by class "VirtualPeriodicAutocorrelations", distance 2.

Methods

plot signature(x = "PeriodicAutocorrelations", y = "missing"): ...

PeriodicAutocovariances-class
Class PeriodicAutocovariances

Description

PeriodicTS-class *Class "PeriodicTS"*

Description

Class "PeriodicTS" is the main class for univariate periodic time series in package "pcts".

Objects from the Class

Objects can be created from numeric vectors and objects from other time series classes by calling [pcts](#) (recommended in most cases).

It is possible also to use calls of the form `new("PeriodicTS", ...)`. This is more useful in programming.

Slots

`.Data`: Object of class "numeric", the core data. Several functions can be used to extract it in various formats, see [Vec](#).

`cycle`: Object of class "BasicCycle", representing the seasonal information, see [pcCycle](#).

`pcstart`: Object of class "ANY", the time of the first observation.

classes [PeriodicTS](#) and [PeriodicMTS](#)

 PeriodicVector-class *Class PeriodicVector*

Description

Objects and methods for class PeriodicVector.

Usage

`PeriodicVector(x, period = length(x))`

Arguments

`x` the values for indices from 1 to period, numeric.
`period` the period, defaults to `length(x)`.

Details

A p -periodic vector, X , is such that $X_{i+pk} = X_i$ for any integers i, k .

Class `PeriodicVector` stores the values of X_1, \dots, X_p and provides indexing methods for extracting and setting its elements.

Value

an object from class `"PeriodicVector"`

Objects from the Class

Objects can be created by calls of the form `new("PeriodicVector", ...)` or more conveniently by using `"PeriodicVector()"`.

Slots

`.Data`: Object of class `"numeric"` ~~
`period`: Object of class `"numeric"` ~~

Extends

Class `"numeric"`, from data part. Class `"vector"`, by class `"numeric"`, distance 2. Class `"atomicVector"`, by class `"numeric"`, distance 2. Class `"index"`, by class `"numeric"`, distance 2.

Class `"numLike"`, by class `"numeric"`, distance 2.

Class `"number"`, by class `"numeric"`, distance 2. Class `"replValue"`, by class `"numeric"`, distance 2.

Methods

`"PeriodicVector"` methods are defined for `"["` and `"[<-"`. Arithmetic operations just inherit the recycling rules from `"numeric"`.

```

[ signature(x = "PeriodicVector", i = "missing", j = "missing", drop = "ANY"): ...
[<- signature(x = "PeriodicVector", i = "ANY", j = "ANY", value = "ANY"): ...
[<- signature(x = "PeriodicVector", i = "missing", j = "ANY", value = "ANY"): ...
```

Author(s)

Georgi N. Boshnakov

See Also[PeriodicVector](#)**Examples**

```

PeriodicVector(1:4, period = 4)
PeriodicVector(1:4) ## same
new("PeriodicVector", 1:4, period = 4)

## if period is given but x is missing, the vector is filled with NA's
PeriodicVector(period = 4)

## this throws error, since length(x) != period:
##   PeriodicVector(1:3, period = 4)

## extract
x <- PeriodicVector(1:4)
x[3:12]
x[c(3, 7, 11, 15)]

# any indices in (-Inf, Inf) work
x[0]
x[-3:0]

## "[<-" works on the underlying vector
x[1] <- 11; x

## modulo indexing works also in assignments:
x[5] <- 21; x

## empty index returns the underlying vector
x[]

## the recycling rule applies on assignment
x[] <- 9; x
x[] <- 1:2; x

## this gives warning, as for numeric vectors
##   x[] <- 8:1
## compare:
##   x <- 1:4
##   x[] <- 8:1

## arithmetic works as usual:
2 * x
x + 1:4
## x + 1:3 # warning - '... a multiple ...'

```

Description

Performs McLeod's test for periodic autocorrelation.

Usage

```
periodic_acf1_test(acf, nepochs)
```

Arguments

acf	sample periodic autocorrelation function
nepochs	the number of epochs used to get the acf

Details

The test statistic is a scaled sum of squares of lag 1 sample periodic autocorrelation coefficients, see McLeod (1993), eq. (5). The distribution is approximately chi-square under the null hypothesis of no periodic autocorrelation.

Value

A list containing the following components:

statistic	the value of the test statistic.
pvalue	the p-value associated with the test statistic.

permean2intercept *Convert between periodic centering and intercepts*

Description

Convert a periodic mean to periodic intercept and vice versa.

Usage

```
permean2intercept(mean, coef, order, nseasons = nrow(coef))
```

```
intercept2permean(intercept, coef, order, nseasons = nrow(coef))
```

Arguments

mean	periodic mean, numeric.
coef	PAR coefficients, matrix.
order	PAR order, vector of positive integers.
nseasons	number of seasons, a.k.a. period.
intercept	periodic intercepts, numeric.

Details

A PAR model can be written in mean corrected or intercept form. `permean2intercept` calculates the intercepts from the means, while `intercept2permean` does the inverse (means from intercepts).

No check is made for periodic stationarity of the model. Converting from mean corrected to intercept form allways succeeds and in fact the means do not need to be means. In the opposite direction there may be problems due to unit roots and similar features.

Value

a numeric vector

Author(s)

Georgi N. Boshnakov

Examples

```
mu <- c(1, 2)
pm1 <- PeriodicArModel(matrix(c(0.5, 0.5), nrow = 2), order = rep(1, 2), sigma2 = 1, mean = mu)

cc <- permean2intercept(mu, pm1@ar@coef, c(1,1))
cc
intercept2permean(cc, pm1@ar@coef, c(1,1))

d <- 4
```

```
mu <- 1:d
co <- rep(0.5, d)
pm1 <- PeriodicArModel(matrix(co, nrow = d), order = rep(1, d), sigma2 = 1, mean = mu)

cc <- permean2intercept(mu, pm1@ar@coef, order = rep(1, d))
cc
intercept2permean(cc, pm1@ar@coef, order = rep(1, d) )
```

permodelmf

Compute the multi-companion form of a per model

Description

Compute the multi-companion form of a per model.

Usage

```
permodelmf(permodel, update = TRUE)
```

Arguments

permodel	a model.
update	If TRUE store the multi-companion form in permodel and return the whole model, otherwise simply return the multi-companion form.

Details

todo:

Value

the multi-companion form of the model or the updated model, as described in Details.

 pi1ar2par

 Convert PIAR coefficients to PAR coefficients

Description

Convert PIAR coefficients to PAR coefficients

Usage

```
pi1ar2par(picoef, parcoef)
piar2par(picoef, parcoef)
```

Arguments

picoef	coefficients of the periodic integration filter, a numeric vector or matrix, see Details.
parcoef	coefficients of the periodically correlated part of the model.

Details

These functions expand periodic filters represented in multiplicative form. The non-periodic analogue of the operation of these functions is representing a multiplicative filter like $(1 - B)(1 - aB)$, where B is the backward shift operator, by the single filter $1 - (1 + a)B + aB^2$, which is just a product of the polynomials, $1 - B$ and $1 - aB$.

In the non-periodic case however this operation is not, in general, equivalent to multiplication of the corresponding polynomials. It is also not commutative.

pi1ar2par converts PIAR(1) model coefficients specified as a set of coefficients corresponding to a periodic unit root and PAR coefficients to coefficients for a single filter.

piar2par does the same but admits higher order periodic integration.

picoef is a matrix, specifying one or more first order periodic unit root filters. Each column contains the coefficients of one filter. If there is only one filter, its coefficients can be given as a numeric vector.

The filters are applied from right to left, in the sense that first the PAR filter is applied to the time series, then the filter specified by the last column and so on.

Value

a matrix, whose i -th row contains the coefficients for the i -th season.

Author(s)

Georgi N. Boshnakov

Examples

```
## Lina's example
parcoef  <- rbind(c(0.5, -0.06), c(0.6, -0.08),
                 c(0.7, -0.1),  c(0.2, 0.15) )
picoef1  <- c(0.8, 1.25, 2, 0.5)
parcoef2 <- pi1ar2par(picoef1, parcoef)

picoef2  <- c(4, 0.25, 5, 0.2)
coefper2I2 <- pi1ar2par(picoef2, parcoef2)
```

pwn_McLeodLjungBox_test

McLeod-Ljung-Box test for periodic white noise

Description

Compute the McLeod-Ljung-Box test statistic for examining the null hypothesis of periodic white noise.

Usage

```
pwn_McLeodLjungBox_test(acf, nepoch, use = 1:maxlag,
  maxlag = ncol(as.matrix(acf)) - 1,
  period = nrow(as.matrix(acf)), fitdf = numeric(period))
```

Arguments

acf	the sample periodic autocorrelation function of the time series.
nepoch	number of cycles used in computing the acf.
use	number of lags to use, may be a vector.
maxlag	maximal lag.
period	number of seasons in a cycle.
fitdf	degrees of freedom corrections for the number of estimated parameters, see Details.

Details

The McLeod-Ljung-Box test can be used to test the null hypothesis of periodic white noise.

If `acf` contains sample autocorrelations of residuals from a fitted model, a correction of the degrees of freedom is strongly recommended.

Argument `fitdf` is a vector specifying how many degrees of freedom to subtract for each season. In the case of PAR models `fitdf` can be set to the PAR orders.

The value of the statistic is set to NA where the correction for degrees of freedom results in negative numbers.

Value

A list containing the following components:

<code>statistic</code>	the value of the test statistic for each lag specified by use.
<code>df</code>	the corresponding degrees of freedom

Note

TODO: Consolidate this and similar tests!

There is a typo in McLeod (1994), eq. (4.5), noted by (McLeod 1995).

 sim_parAcvf

Create a random periodic autocovariance function

Description

Select randomly a periodic autoregression model and return the periodic autocovariances associated with it.

Usage

```
sim_parAcvf(period, order, sigma2)
```

Arguments

period	the period, a positive integer.
order	the AR order, a vector of non-negative integers.
sigma2	the variances of the innovations, a numeric vector of length period (todo: or one?).

Details

Uses `sim_parCoef()` to generate a random PAR model.

Value

an object of class "matrix". In addition, the specification of the model is in attribute "model" which is a list with the following components:

ar	a matrix, the coefficients of the PAR model,
sigma2	numeric, the innovation variances,
order	the PAR order.

sim_parCoef	<i>Generate a periodic autoregression model</i>
-------------	---

Description

Generate a periodic autoregression model, possibly integrated.

Usage

```
sim_parCoef(period, n.root, sigma2 = rep(1, period), ...)
```

Arguments

period	number of seasons in a cycle.
n.root	number of non-zero roots, see details.
sigma2	variances of the innovations.
...	additional arguments to be passed down to <code>sim_pcfilter</code>

Details

`sim_parCoef` uses the multi-companion method to generate the model. The function is essentially a wrapper for `sim_pcfilter`.

The order of the filter is set to `n.root` for each season. Part of the spectral information may be specified with the "..." arguments, see [sim_pcfilter](#) and [sim_mc](#) for a discussion of this.

Value

a periodic autoregression model as a list with elements:

ar	a matrix whose <i>i</i> th row contains the coefficients for the <i>i</i> season,
sigma2	the innovation variances, a numeric vector.

Author(s)

Georgi N. Boshnakov

  eigsign = c(pi/2, 1, -1, 1, -1))
```

sim_pc

Simulate periodically correlated ARMA series

Description

Simulate a realization of a periodically correlated arma model or a continuation of an existing series. Initial values may be given too.

Usage

```
sim_pc(model, n = NA, randgen = rnorm, seasonof1st = 1, nepochs = NA,
  n.start = NA, x, eps, nmean = NULL, nintercept = NULL, ...)
```

Arguments

model	a list with elements phi, theta, p, q, period, mean, intercept, specifying the model.
n	length of the series.
randgen	random number generator as required by sim_pwn .
seasonof1st	season of the first value.
nepochs	number of epochs; if nepochs is given, then n is computed as <i>nepochs*period</i> .
n.start	burn-in number; generate n.start + n observations and discard the first n.start of them, see Details.
x	<i>initial</i> or <i>before</i> values, see Details.
eps	innovations, see Details.
nmean	a vector of length n of means, see Details.
nintercept	a vector of length n of intercepts, see Details.
...	any additional arguments to be passed on to sim_pwn .

Details

Argument `x` can be used to specify two types of initialisation values - 'before' and 'init'. They are used similarly in computations but 'before' values are not included in the result, while 'init' values are (unless dropped due to `n.start`). 'Before' values provide a convenient way to simulate continuation trajectories for a time series, for example for simulation based prediction intervals.

If `x` is "numeric", it represents 'before' values. Alternatively, `x` can be a list with components "before" and "init".

Innovations are usually generated with the random number generator specified by `randgen` (with default `rnorm`) and the ... parameters by a call to the function `sim_pwn`, see the documentation for `sim_pwn` for various ways to control the distribution of the generated sequence.

The innovations can also be generated in advance and supplied using argument `eps`. If `eps` is numeric, it is taken to represent the innovations. Alternatively, `eps` can be a list with the innovations in component "main". This list may also contain components "before" and/or "init" specifying 'before' or 'initial' values, with interpretation as for `x`.

`nintercept` can be used to specify trend representing the effect of time and/or covariates. As for `eps`, if it is numeric it is taken to represent the main values. It can also be a list with components `before`, `init`, and `main`.

To avoid ambiguity, let's reiterate that *before* values are past values of the corresponding quantity (before the start of the simulated series), while *init* values are "initial" values. In particular, if initial values are specified for `x`, these will form the start of the generated series (unless `n.start` leads to them being discarded).

If *before* values are specified for the series and the innovations, then they play a role analogous to that of initial values, so it does not make much sense to supply also *initial* values.

The function effectively does the following. `innov` is generated if not supplied, a vector of innovations is created `eps <- c(innovbefore, innovinit, innov)`, a vector `x` is created of the same length as `eps`, and initialised with `xbefore` and `xinit`. If there are no initial or before values, these are assumed to be 0. The remaining values of `x` are filled using the pc-arma equations. Finally, the `xbefore` values are discarded as well as the first `n.start` values.

`n.start` should usually be a multiple of the period since otherwise the first observation in the returned vector will not correspond to `seasonof1st`.

`sim_pc` deals mainly with the interpretation of the parameters. The actual computations are done by `pc.filter`. Moreover, `sim_pc` does not look at the model. It knows only about `model$period` and uses it to compute `n` if `n` is not specified. (It probably should not care even about this.)

Value

numeric, the simulated time series

To do

option to return the innovation sequence; option to include the before values.

option to return the season of the first value in the returned series (it may be different from `seasonof1st` due to `n.start`).

sim_pwn *Simulate periodic white noise*

Description

Simulate periodic white noise.

Usage

```
sim_pwn(n = 100, period = NA, seasonof1st = 1, scale = NULL,
        shift = NULL, f = rnorm, ...)
```

Arguments

n	length of the generated sample.
period	number of seasons in an epoch.
seasonof1st	season of the first observation in the result.
scale	scale the series by this amount, a vector of length period or 1.
shift	shift the series by this amount, a vector of length period or 1.
f	a function or list of functions to generate random numbers.
...	arguments for the random number generator(s) specified by f.

Details

First a series, say x , of random numbers is generated as requested by the argument `f`. Then, if `shift` and/or `scale` are supplied, the values are modified as follows:

$$y_t = shift_k + scale_k x_t$$

where k is the season corresponding to time t . The vector y is returned.

If `f` is a single a function (or name of a function), then the series is generated (effectively) by the call `f(n, ...)`.

The argument `f` may also be a list whose k th element is itself a list specifying the random number generator for the k th season. The first element being the function (such as `rnorm`) and the remaining elements being parameters for that function. Parameters common to all seasons may be supplied through the `...` argument.

The argument `period` may be omitted. In that case it is inferred from `f` and/or the lengths of `shift` and `scale`. Currently there is no check for consistency here.

The arguments `shift` and `scale` may be used to specify simple linear transformations of the generated values, possibly different for the different seasons. Each of them should be a vector of length `period` or one.

`seasonof1st` can be used to request the simulated time series to start from a season other than the first one. Note that whatever the value of `seasonof1st`, the first elements of `scale`, `shift` and `f` (if a list) are taken to refer to season one.

Value

A vector of length n representing a realization of a periodic white noise series. The season of the first observation is `seasonof1st`.

Level

0 (base)

Author(s)

Georgi N. Boshnakov

Examples

```
## three equivalent ways to specify periodic white noise with
## normal innovatios, 2 seasons, s.d. = 0.5 for season 1, and 2 for season 2
sim_pwn(100, f = rnorm, scale = c(0.5, 2))
sim_pwn(n = 100, scale = c(0.5, 2)) # rnorm is the default generator
sim_pwn(100, f = list(c(rnorm, 0, 0.5), c(rnorm, 0, 2)))
```

 sl_utils

Functions for some basic operations with seasons

Description

Functions for some basic operations with seasons.

Usage

```
toSeason(t, period, t1 = 1, from = 1)
toSeasonPair(t, s, period, ...)
ttTosl(r, period)
ttmatToslPairs(i, j, period)
```

Arguments

r	covariance matrix, see ‘Details’.
t	a vector of integers, representing times.
s	a vector of integers, representing times.
period	the number of seasons.
t1	time corresponding to the first season, an integer number.
from	1 or 0, depending on whether the season numbers start from 1 or 0.
i	a vector of integers.
j	a vector of integers.
...	todo: describe!

Details

`ttmatToslPairs(i, j, period)` transforms time-time pairs to season-lag pairs. The time pairs are obtained by pairing each element of `i` with each element of `j`. A four column matrix is created with one row for each pair (t, s) , such that $t=i[m]$ and $s=j[n]$ for some m and n . The row is m, n, s, l , where (s, l) is the season-lag pair corresponding to (t, s) .

`ttTosl(r, period)` converts autocovariances given in a covariance matrix (i.e. in “`tt`” form) to the “`sl`” form. The result is a `period` x `(maxlag+1)` matrix, where `maxlag` is the maximal lag available

in r . Entries for which no values are available are filled with NA's. Warning is given if contradictory entries are found (i.e. if r is not from a periodically correlated process with the given period).

`toSeason(t, period, t1=1, from=1)` returns the season corresponding to t . $t1$ is a time (integer) whose season is the first season, $from$ is 1 if the numbering of seasons is 1,2,...,period, or 0 if the numbering of seasons is 0,1,...,period-1. Other values for $from$ are not admissible (but not checked).

Note: some of the functions in this package implicitly assume that $t1=1$ and $from=1$.

`toSeasonPair(t, s, period)` converts the "tt" pair t, s to "sl" pair and returns the result in the form of a list with elements `season` and `lag`. Currently t and s must be scalars.

`pc.omitneg` helps to implement dropping of negative indices in season-lag objects. It returns its first argument, `lags`, if all of its elements are non-negative. Otherwise, all elements of `lags` must be non-positive. In this case the function creates the vector $\emptyset : \text{maxlag}$ and drops the elements specified by `lags`. Note that the default indexing will not work properly since zero elements in an index are omitted (and there are such indices in season-lag objects).

Value

for `ttmatToslPairs`, a matrix with four columns;

for `ttTosl`, a matrix with period rows;

for `toSeason(t, period, t1=1, from=1)`, a vector of integers;

for `toSeasonPair(t, s, period)`, a list with elements `season` and `lag`;

for `pc.omitneg`, a vector of lags (non-negative integers).

Note

2013-10-24 - Corrected the description of the return value of `ttmatToslPairs`. It incorrectly stated that the first two columns are "tt" pair (they are actually indices in i and j).

SubsetPM-class

Class SubsetPM

Description

Class "SubsetPM" - subset PAR models with trigonometric parameterisation.

Objects from the Class

Objects can be created by calls of the form `new("SubsetPM", ...)` but they are typically created by model fitting functions, see the examples.

Slots

`theTS`: "ANY", the time series to which the model is fitted.

`period`: "integer", the period.

`order`: "integer", the order.

`findex`: "function".

`harmonics`: "integer", Fourier harmonics to include in the model.

`call`: "call", the call used to fit the model.

`other`: "namedList".

Methods

```

coef signature(object = "SubsetPM"): ...
fitted signature(object = "SubsetPM"): ...
residuals signature(object = "SubsetPM"): ...

test_piar	<i>Test for periodic integration</i>
-----------	--------------------------------------

Description

Test if a time series is periodically integrated.

Usage

```
test_piar(x, d, p, sintercept = FALSE, sslope = FALSE, homoschedastic = FALSE)
```

Arguments

x	time series.
d	period.
p	autoregressive order, a positive integer.
sintercept	if TRUE, include seasonal intercept.
sslope	if TRUE, include seasonal slope.
homoschedastic	if TRUE, assume the innovations variance is the same for all seasons.

Details

Computes test statistics for Franses (1996) test for periodic integration of order 1. The test is based on periodic autoregression of order p, where p can be any positive integer.

Value

a list with the following components:

p	autoregressive order.
spec	values of sintercept, sslope, and homoschedastic, a named logical vector.
statistics	a matrix containing the test statistics (first row) and the corresponding p-values (second row). "LR" is not normalised, so its p-value is NA.

Note

Currently only the case $p = 1$ is handled, for $p > 1$ the statistics are set to NA. **:TODO: handle this.**
All statistics are computed but some p-values are not computed yet.

Vec

*Core data of periodic time series***Description**

Extract the core data from a periodic time series as a vector, matrix or array.

Usage

```
Vec(x, ...)
```

```
tsMatrix(x, ...)
```

```
tsVector(x, ...)
```

```
tsVec(x, ...)
```

```
pcMatrix(x, ...)
```

```
pcArray(x, ndim = 3, ...)
```

```
pctsArray(x, ndim = 3, ...)
```

Arguments

<code>x</code>	an object.
<code>...</code>	further arguments for methods.
<code>ndim</code>	currently not used.

Details

These functions give the core data in various common forms.

The data values can be extracted as a vector from a periodic time series object, say `x`, with `as.vector(x)` or `as(x, "vector")`. For multivariate time series the vector returned by `as.vector(x)` (or `as(x, "vector")`) is equivalent to `as.vector(as.matrix(x))`.

Similarly, `as.matrix()` and `as(x, "matrix")` extract the data as a matrix containing one column per variable.

`Vec()` is like `as.vector()` but the result is a matrix with one column (column vector). The default does literally this. Thus both, `Vec()` and `as.vector()`, implement the **Vec** operation from matrix calculus but the latter returns the result as a vector, not matrix.

The most common representation of data in statistics is matrix-like with one column per variable. The descriptions of algorithms for multivariate time series however usually define the vector of observations at a given time to be a column vector. In particular, implementations of the Kalman filter often require precisely this arrangement. In that case the data matrix is the transposed of the more common one and the vectorising operation stacks the observations, not the variables.

The functions `tsMatrix()`, `tsVector()` and `tsVec()` provide the analogues of `as.vector()`, `as.matrix()` and `Vec()` for the “transposed” arrangement.

These functions may look redundant since they are simple combinations of the above and transpose operations. Having functions makes for more readable programming. They may be more efficient, as well, for example if the underlying time series class stores the data in the transposed format.

`pcMatrix()` and `pcArray()` also give the core data. Effectively, they give an additional dimension to the seasons. The season becomes the first dimension since for column oriented data the season changes fastest. `pcMatrix` is most suitable for univariate time series, `pcArray()` for multivariate. Note that `pcArray()` easily extends to multiple periodicities although currently (2019-04-19) there are no methods that exploit this.

For univariate time series, in the matrix returned by `pcMatrix()` each row represents the data for one season and each column for one cycle. For multivariate time series, the matrices for each variable are put next to each other.

`pcArray()` returns the data as an array, whose last dimension corresponds to variables. In the default case the array is 3-dimensional with dimensions (season, year, variable).

`pctsArray()` is a variant of `pcArray()` corresponding to the arrangement of `tsMatrix()`. The ordering of the dimensions here is (variable, season, cycle).

Value

vector, matrix or array, as indicated by the name of the function and described in section ‘Details’.

Periodic methods for base R functions

Description

Periodic methods for base R functions.

Usage

```

## S3 method for class 'PeriodicTS'
window(x, start = NULL, end = NULL, seasons = NULL, ...)

## S3 method for class 'PeriodicMTS'
window(x, start = NULL, end = NULL, seasons = NULL, ...)

## S3 method for class 'PeriodicTS'
na.trim(object, sides = c("both", "left", "right"), ...)

## S3 method for class 'PeriodicMTS'
na.trim(object, sides = c("both", "left", "right"),
        is.na = c("any", "all"), ...)

## S3 method for class 'PeriodicTimeSeries'
frequency(x, ...)

## S3 method for class 'PeriodicTimeSeries'
deltat(x, ...)

## S3 method for class 'PeriodicTimeSeries'
cycle(x, ...)

```

```
## S3 method for class 'PeriodicTimeSeries'
time(x, offset = 0, ...)

## S3 method for class 'Cyclic'
start(x, ...)

## S3 method for class 'Cyclic'
end(x, ...)
```

Arguments

<code>x</code> , object	an object from the indicated periodic class.
<code>start</code>	numeric(2), start time.
<code>end</code>	numeric(2), end time.
<code>seasons</code>	numeric, a subset of 1:nSeasons(x).
<code>...</code>	Not used by these methods.
<code>sides</code>	which side to trim: start ("left"), end ("right"), or both ("both").
<code>is.na</code>	for multivariate time series: if "all", the observation at time t will be considered missing only if all variables are NA at that time. Otherwise, if "any", any variable with value NA will cause the observation at time t to be considered missing.
<code>offset</code>	currently ignored (:TODO:)

Details

Periodic methods for base R and other common functions for manipulation of time series. These methods work analogously to their base R cousins and only the differences, if any, are discussed below.

`window` takes a part of `x`, preserving the class of the object. Argument `seasons` selects a subset of the seasons.

`na.trim` is a function defined in package `zoo` and re-exported by `pcts`. It trims NAs from one or both ends of the time series, as requested by the arguments. The arguments of the methods defined by `pcts` have the same meaning as those in `zoo`.

Value

for `window` and `na.trim`, an object from the same class as the original, representing the requested part of the time series.

for `frequency`, an integer number.

for `deltat`, a number (1/frequency).

for `cycle` and `time`, a "PeriodicTS" object.

for `start` and `end`, time of first/last observation, encoded as a pair of numbers.

See Also

[window](#), [frequency](#), [na.trim](#) for details on what these functions do.
[availStart](#) and [availEnd](#) give the times of the first and last non-NA observations.

Examples

```
pres <- pcts(presidents)
head(pres, 8)
availStart(pres)

zoo-class

Class zoo made S4

Description

Class zoo made S4

Objects from the Class

A virtual Class: No objects may be created from it.

S4 Class "zoo" is derived from its namesake in package **zoo** for use as a super class for periodic time series classes and in S4 method signatures.

Slots

.S3Class: Object of class "character" ~~

Extends

Class "[oldClass](#)", directly.

Methods

No methods defined with class "zoo" in the signature.

See Also

[PeriodicTS_zooreg](#), [zooreg](#) and package **zoo**

Examples

```
showClass("zoo")
```

zooreg-class	<i>Virtual S4 class zooreg</i>
--------------	--------------------------------

Description

Virtual S4 class zooreg.

Objects from the Class

A virtual Class: No objects may be created from it.

S4 Class "zooreg" is derived from its namesake in package **zoo** for use as a super class for periodic time series classes and in S4 method signatures.

Slots

.S3Class: Object of class "character" ~~

Extends

Class "[zoo](#)", directly. Class "[oldClass](#)", by class "zoo", distance 2.

Methods

No methods defined with class "zooreg" in the signature.

See Also

[PeriodicTS_zooreg](#), [zoo](#) and package **zoo**

Examples

```
showClass("zooreg")
```
